3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/ Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** — **Description** 0x0 — No Interrupt 0x1 — Transfer Completed Interrupt	RO	0x0

doeptsiz3

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doeptsiz3 Fields

Bit	Name	Description	Access	Reset
30:29	rxdpid	Applies to isochronous OUT endpoints only.This is the data PID received in the last packet for this endpoint. Use datax. Applies to control OUT Endpoints only. Use packetx. This field specifies the number of back-to-back SETUP data packets the endpoint can receive. **Value** / **Description** 0x0 DATA0 0x1 DATA2 or 1 packet 0x2 DATA1 or 2 packets 0x3 MDATA or 3 packets	RO	0x0
28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the RxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the RxFIFO.	RW	0x0

doepctl4 Fields

Bit	Name	Description	Access	Reset
31	`epena`	Applies to IN and OUT endpoints. -When Scatter/ Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/ Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — Endpoint Enable inactive 0x1 — Endpoint Enable active	RO	0x0
30	`epdis`	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — No Endpoint Disable 0x1 — Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	`setd1pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	WO	0x0
28	`setd0pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/ Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/ Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Enables Endpoint Data PID to DATA0)	WO	0x0
27	`snak`	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	WO	0x0
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	RO	0x0
20	`snp`	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** — **Description** 0x0 — Disable Snoop Mode 0x1 — Enable Snoop Mode	RW	0x0
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — Not Active 0x1 — USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

Doepint4

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address
`usb0`	`0xFFB00000`	`0xFFB00B88`
`usb1`	`0xFFB40000`	`0xFFB40B88`

Offset: `0xB88`

Doepint4 Fields

Bit	Name	Description	Access	Reset
14	`nyetintrpt`	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	`nakintrpt`	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	`bbleerr`	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	`pktdrpsts`	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/ Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz4

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — Endpoint Enable inactive 0x1 — Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — No Endpoint Disable 0x1 — Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. Value / Description 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value / Description 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. Value / Description 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. Value / Description 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — Not Active 0x1 — USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint5

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint5 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	`outpkterr`	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	`back2backsetup`	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	`stsphsercvd`	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** / **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** / **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** / **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** / **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** — **Description** 0x0 — No Interrupt 0x1 — Transfer Completed Interrupt	RO	0x0

doeptsiz5

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/ Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/ Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled - Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — Endpoint Enable inactive 0x1 — Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — No Endpoint Disable 0x1 — Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/ Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/ Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. **Value** / **Description** 0x0 No Clear NAK 0x1 Clear NAK	`WO`	`0x0`
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** / **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	`RO`	`0x0`
20	`snp`	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** / **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	`RW`	`0x0`
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** / **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	`RW`	`0x0`

10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint6

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint6 Fields

Bit	Name	Description	Access	Reset
14	`nyetintrpt`	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — NYET Interrupt	RO	0x0
13	`nakintrpt`	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — No interrupt 0x1 — NAK Interrupt	RO	0x0
12	`bbleerr`	The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — BbleErr interrupt	RO	0x0
11	`pktdrpsts`	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** — **Description** 0x0 — No interrupt 0x1 — Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — No interrupt 0x1 — BNA interrupt	RO	0x0
8	`outpkterr`	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** — **Description** 0x0 — No OUT Packet Error 0x1 — OUT Packet Error	RO	0x0
6	`back2backsetup`	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** — **Description** 0x0 — No Back-to-Back SETUP Packets Received 0x1 — Back-to-Back SETUP Packets Received	RO	0x0
5	`stsphsercvd`	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** — **Description** 0x0 — No Status Phase Received for Control Write 0x1 — Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz6

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doeptsiz6 Fields

Bit	Name	Description	Access	Reset
30:29	rxdpid	Applies to isochronous OUT endpoints only.This is the data PID received in the last packet for this endpoint. Use datax. Applies to control OUT Endpoints only. Use packetx. This field specifies the number of back-to-back SETUP data packets the endpoint can receive. **Value** — **Description** 0x0 — DATA0 0x1 — DATA2 or 1 packet 0x2 — DATA1 or 2 packets 0x3 — MDATA or 3 packets	RO	0x0
28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the RxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the RxFIFO.	RW	0x0

doepctl7 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/ Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/ Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled - Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** / **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** / **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	`setd1pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	WO	0x0
28	`setd0pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Endpoint Data PID to DATA0)	WO	0x0
27	`snak`	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	`WO`	`0x0`
25:22	`txfnum`	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	`RW`	`0x0`
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	`RO`	`0x0`

Bit	Name	Description	Access	Reset
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** / **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0
17	naksts	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** / **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** / **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** / **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint7

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

doepint7 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — NYET Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** / **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** / **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** / **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** / **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0

Bit	Name	Description	Access	Reset
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0

Bit	Name	Description	Access	Reset
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** — **Description** 0x0 — No SETUP Phase Done 0x1 — SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** — **Description** 0x0 — No Interrupt 0x1 — AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — No Interrupt 0x1 — Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** — **Description** 0x0 — No Interrupt 0x1 — Transfer Completed Interrupt	RO	0x0

doeptsiz7

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** — **Description** 0x0 — Disable Snoop Mode 0x1 — Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	`naksts`	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	`RO`	`0x0`
16	`dpid`	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	`RO`	`0x0`

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint8

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
4	`outtknepdis`	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	`setup`	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	`epdisbld`	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/ Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz8

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepctl9 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/ Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/ Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** / **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** / **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/ Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/ Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

doepint9

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint9 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** / **Description** 0x0: No interrupt 0x1: NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** / **Description** 0x0: No interrupt 0x1: NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** / **Description** 0x0: No interrupt 0x1: BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** / **Description** 0x0: No interrupt 0x1: Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** / **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** / **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** / **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** / **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/ Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz9

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

</table>

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** / **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** / **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** / **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** / **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	`naksts`	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	`dpid`	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint10

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint10 Fields

Bit	Name	Description	Access	Reset
14	`nyetintrpt`	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	`RO`	`0x0`
13	`nakintrpt`	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	`RO`	`0x0`
12	`bbleerr`	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	`RO`	`0x0`
11	`pktdrpsts`	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	`RO`	`0x0`

Bit	Name	Description	Access	Reset
9	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	`outpkterr`	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	`back2backsetup`	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	`stsphsercvd`	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

<table>

</table>

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/ Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz10

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint11

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint11 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — No interrupt 0x1 — NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** — **Description** 0x0 — No interrupt 0x1 — Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/ Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** — **Description** 0x0 — No Interrupt 0x1 — Transfer Completed Interrupt	RO	0x0

doeptsiz11

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

</table>

Bit	Name	Description	Access	Reset
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** / **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/ Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/ Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** / **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** / **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. **Value** / **Description** 0x0 No Clear NAK 0x1 Clear NAK	`WO`	`0x0`
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** / **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	`RO`	`0x0`
20	`snp`	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** / **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	`RW`	`0x0`
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** / **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	`RW`	`0x0`

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint12

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint12 Fields

Bit	Name	Description	Access	Reset
14	`nyetintrpt`	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — NYET Interrupt	RO	0x0
13	`nakintrpt`	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — No interrupt 0x1 — NAK Interrupt	RO	0x0
12	`bbleerr`	The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — BbleErr interrupt	RO	0x0
11	`pktdrpsts`	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** — **Description** 0x0 — No interrupt 0x1 — Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	`outpkterr`	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	`back2backsetup`	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	`stsphsercvd`	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/ Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz12

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepdma12 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma12	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — Not Active 0x1 — USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint13

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint13 Fields

Bit	Name	Description	Access	Reset
14	`nyetintrpt`	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** / **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	`nakintrpt`	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** / **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	`bbleerr`	The core generates this interrupt when babble is received for the endpoint. **Value** / **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	`pktdrpsts`	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** / **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	`outtknepdis`	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** — **Description** 0x0 — No OUT Token Received When Endpoint Disabled 0x1 — OUT Token Received When Endpoint Disabled	RO	0x0
3	`setup`	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** — **Description** 0x0 — No SETUP Phase Done 0x1 — SETUP Phase Done	RO	0x0
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** — **Description** 0x0 — No Interrupt 0x1 — AHB Error interrupt	RO	0x0
1	`epdisbld`	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — No Interrupt 0x1 — Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/ Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** — **Description** 0x0 — No Interrupt 0x1 — Transfer Completed Interrupt	RO	0x0

doeptsiz13

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepint14

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address

doepint14 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** / **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** / **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** / **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** / **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** / **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	`outpkterr`	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** / **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	`back2backsetup`	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** / **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	`stsphsercvd`	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** / **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** / **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
3	setup	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** / **Description** 0x0 No SETUP Phase Done 0x1 SETUP Phase Done	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** / **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** / **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz14

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepctl15 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** / **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** / **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	`setd1pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	`WO`	`0x0`
28	`setd0pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Enables Endpoint Data PID to DATA0)	`WO`	`0x0`
27	`snak`	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	`WO`	`0x0`

</table></td><td>RW</td><td>0x0</td></tr>
</table>

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint15

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepdma15 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma15	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

Power and Clock Gating Register Register Descriptions

There is a single register for power and clock gating. It is available in both Host and Device modes.

Offset: 0xe00

pcgcctl on page 18-796
This register is available in Host and Device modes. The application can use this register to control the core's power-down and clock gating features. Because the CSR module is turned off during power-down, this register is implemented in the AHB Slave BIU module.

USB Data FIFO Address Map

These regions, available in both Host and Device modes, are a push/pop FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.

SPI Controller 19

2014.06.30

cv_54019 Subscribe Send Feedback

The hard processor system (HPS) provides two serial peripheral interface (SPI) masters and two SPI slaves. The SPI masters and slaves are instances of the Synopsys® DesignWare® Synchronous Serial Interface (SSI) controller (DW_apb_ssi). †[42]

Features of the SPI Controller

The SPI controller has the following features: †

- Serial master and serial slave controllers – Enable serial communication with serial-master or serial-slave peripheral devices. †
- Serial interface operation – Programmable choice of the following protocols:
  - Motorola SPI protocol
  - Texas Instruments Synchronous Serial Protocol
  - National Semiconductor Microwire
- DMA controller interface integrated with HPS DMA controller
- SPI master supports `rxd` sample delay
- Transmit and receive FIFO buffers are 256 words deep
- SPI master supports up to four slave selects
- Programmable master serial bit rate
- Programmable data item size of 4 to 16 bits

SPI Block Diagram and System Integration

The SPI supports data bus widths of 32 bits. †

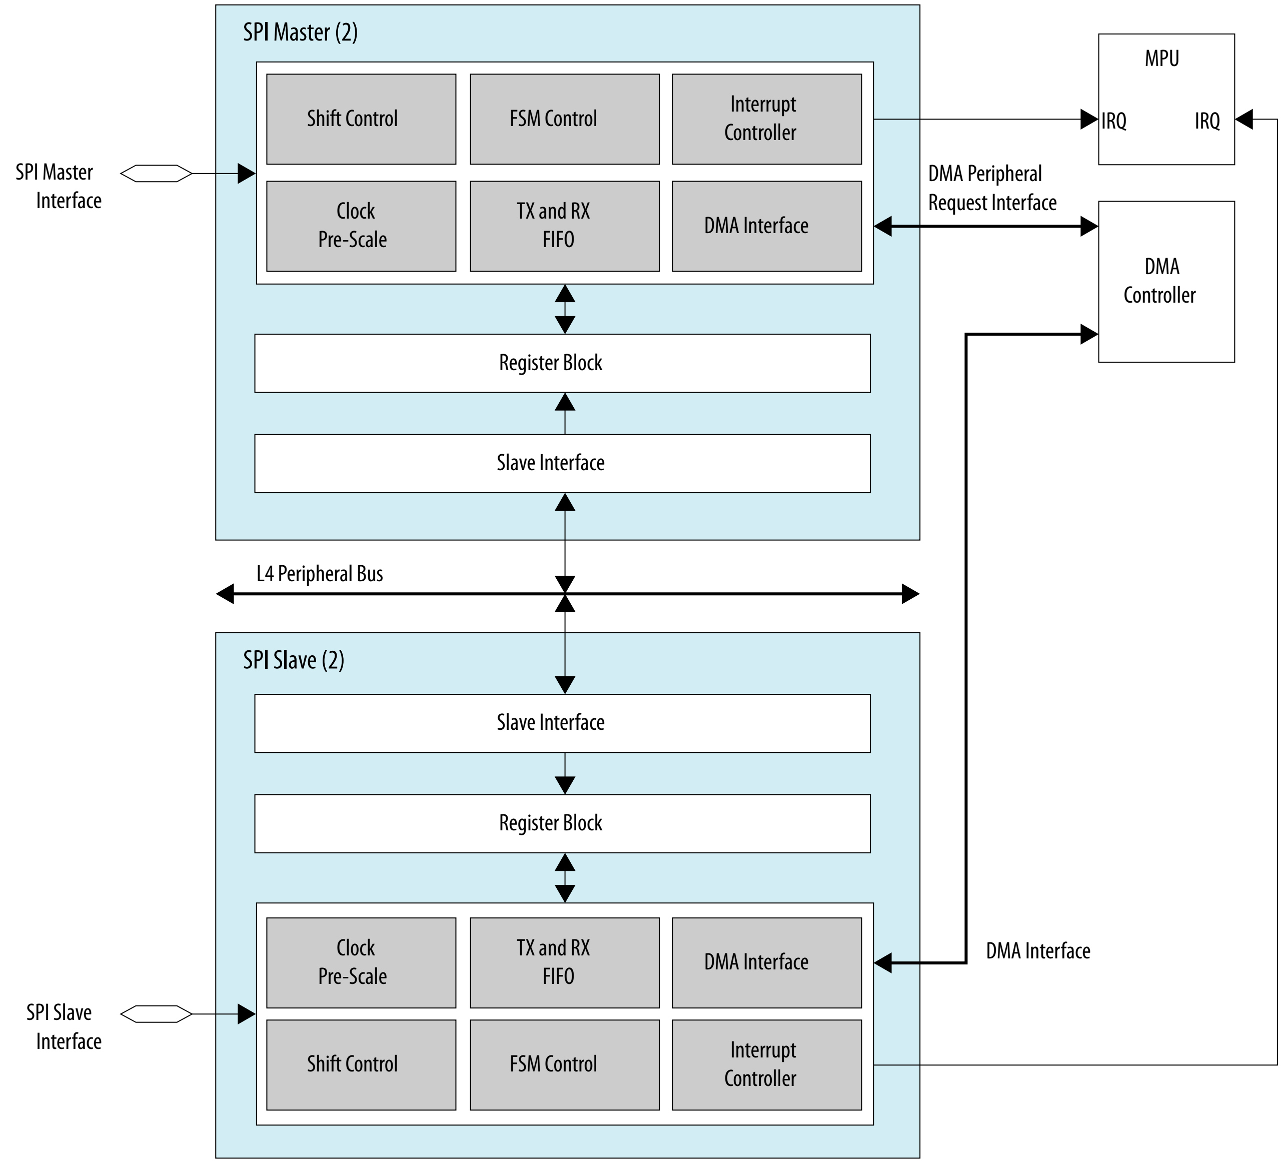
SPI Block Diagram

Figure 19-1: SPI Block Diagram



The functional groupings of the main interfaces to the SPI block are as follows: †

- System bus interface
- DMA peripheral request interface
- Interrupt interface
- SPI interface

Functional Description of the SPI Controller

Protocol Details and Standards Compliance

This chapter describes the functional operation of the SPI controller. †

The host processor accesses data, control, and status information about the SPI controller through the system bus interface. The SPI also interfaces with the DMA Controller. †

The HPS includes two general-purpose SPI master controllers and two general-purpose SPI slave controllers.

The SPI controller can connect to any other SPI device using any of the following protocols:

- Motorola SPI Protocol †
- Texas Instruments Serial Protocol (SSP) †
- National Semiconductor Microwire Protocol †

SPI Controller Overview

In order for the SPI controller to connect to a serial-master or serial-slave peripheral device, the peripheral must have a least one of the following interfaces: †

- Motorola SPI protocol – A four-wire, full-duplex serial protocol from Motorola. The slave select line is held high when the SPI controller is idle or disabled. For more information, refer to “Motorola SPI Protocol”. †
- Texas Instruments Serial Protocol (SSP) – A four-wire, full-duplex serial protocol. The slave select line used for SPI and Microwire protocols doubles as the frame indicator for the SSP protocol. For more information, refer to “Texas Instruments Synchronous Serial Protocol (SSP)”. †
- National Semiconductor Microwire – A half-duplex serial protocol, which uses a control word transmitted from the serial master to the target serial slave. For more information, refer to “National Semiconductor Microwire Protocol”. You can program the FRF (frame format) bit field in the Control Register 0 (`CTRLR0`) to select which protocol is used. †

The serial protocols supported by the SPI controller allow for serial slaves to be selected or addressed using hardware. Serial slaves are selected under the control of dedicated hardware select lines. The number of select lines generated from the serial master is equal to the number of serial slaves present on the bus. The serial-master device asserts the select line of the target serial slave before data transfer begins. This architecture is illustrated in part A in the following figure. †

When implemented in software, the input select line for all serial slave devices should originate from a single slave select output on the serial master. In this mode it is assumed that the serial master has only a single slave select output. If there are multiple serial masters in the system, the slave select output from all masters can be logically ANDed to generate a single slave select input for all serial slave devices. †

The main program in the software domain controls selection of the target slave device; this architecture is illustrated in part B of the Hardware/Software Slave Selection diagram Software would control which slave is to respond to the serial transfer request from the master device. †

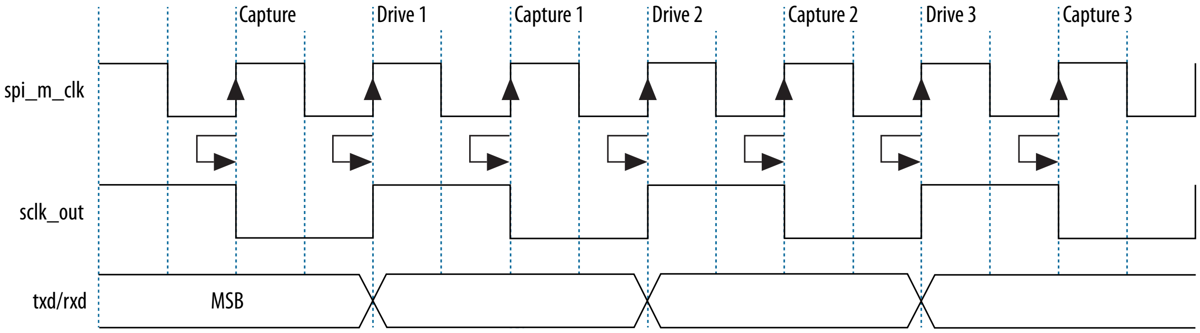
Serial Bit-Rate Clocks

SPI Master Bit-Rate Clock

The maximum frequency of the SPI master bit-rate clock (`sclk_out`) is one-half the frequency of SPI master clock (`spi_m_clk`). This allows the shift control logic to capture data on one clock edge of `sclk_out` and propagate data on the opposite edge. The `sclk_out` line toggles only when an active transfer is in progress. At all other times it is held in an inactive state, as defined by the serial protocol under which it operates. †

Figure 19-3: Maximum sclk_out/spi_m_clk Ratio



The frequency of `sclk_out` can be derived from the equation below, where <*SPI clock*> is `spi_m_clk` for the master SPI modules and `l4_main_clk` for the slave SPI modules. †

$F_{sclk\_out} = F_{<SPI\ clock>} / \mathrm{SCKDV}$

`SCKDV` is a bit field in the register `BAUDR`, holding any even value in the range 2 to 65,534. If `SCKDV` is 0, then `sclk_out` is disabled. †

The following equation describes the frequency ratio restrictions between the bit-rate clock `sclk_out` and the SPI master peripheral clock. The SPI master peripheral clock must be at least double the offchip master clock. †

Table 19-1: SPI Master Peripheral Clock

• SPI Master Peripheral Clock
$F_{spi\_m\_clk}$ >= 2 x (maximum $_{Fsclk\_out}$) †

SPI Slave Bit-Rate Clock

The minimum frequency of `l4_main_clk` depends on the operation of the slave peripheral. If the slave device is *receive only*, the minimum frequency of `l4_main_clk` is six times the maximum expected frequency of the bit-rate clock from the master device (`sclk_in`). The `sclk_in` signal is double synchronized to the `l4_main_clk` domain, and then it is edge detected; this synchronization requires three `l4_main_clk` periods. †

If the slave device is *transmit and receive*, the minimum frequency of `l4_main_clk` is eight times the maximum expected frequency of the bit-rate clock from the master device (`sclk_in`). This ensures that data on the master `rxd` line is stable before the master shift control logic captures the data. †

The frequency ratio restrictions between the bit-rate clock `sclk_in` and the SPI slave peripheral clock are as follows: †

- Slave (receive only): $F_{l4\_main\_clk}$ >= 6 x (maximum $_{Fsclk\_in}$) †
- Slave: Fl4_main_clk >= 8 x (maximum Fsclk_in) †

Transmit and Receive FIFO Buffers

There are two 16-bit FIFO buffers, a transmit FIFO buffer and a receive FIFO buffer, with a depth of 256. Data frames that are less than 16 bits in size must be right-justified when written into the transmit FIFO buffer. The shift control logic automatically right-justifies receive data in the receive FIFO buffer. †

Each data entry in the FIFO buffers contains a single data frame. It is impossible to store multiple data frames in a single FIFO buffer location; for example, you may not store two 8-bit data frames in a single FIFO buffer location. If an 8-bit data frame is required, the upper 8-bits of the FIFO buffer entry are ignored or unused when the serial shifter transmits the data. †

The transmit and receive FIFO buffers are cleared when the PI controller is disabled (`SSIENR=0`) or reset.

The transmit FIFO buffer is loaded by write commands to the SPI data register (`DR`). Data are popped (removed) from the transmit FIFO buffer by the shift control logic into the transmit shift register. The transmit FIFO buffer generates a transmit FIFO empty interrupt request when the number of entries in the FIFO buffer is less than or equal to the FIFO buffer threshold value. The threshold value, set through the register `TXFTLR`, determines the level of FIFO buffer entries at which an interrupt is generated. The threshold value allows you to provide early indication to the processor that the transmit FIFO buffer is nearly empty. A Transmit FIFO Overflow Interrupt is generated if you attempt to write data into an already full transmit FIFO buffer. †

Data are popped from the receive FIFO buffer by read commands to the SPI data register (`DR`). The receive FIFO buffer is loaded from the receive shift register by the shift control logic. The receive FIFO buffer generates a receive FIFO full interrupt request when the number of entries in the FIFO buffer is greater than or equal to the FIFO buffer threshold value plus one. The threshold value, set through register `RXFTLR`, determines the level of FIFO buffer entries at which an interrupt is generated. †

The threshold value allows you to provide early indication to the processor that the receive FIFO buffer is nearly full. A Receive FIFO Overrun Interrupt is generated when the receive shift logic attempts to load data into a completely full receive FIFO buffer. However, the newly received data are lost. A Receive FIFO Underflow Interrupt is generated if you attempt to read from an empty receive FIFO buffer. This alerts the processor that the read data are invalid. †

SPI Interrupts

The SPI controller supports combined interrupt requests, which can be masked. The combined interrupt request is the ORed result of all other SPI interrupts after masking. All SPI interrupts have active-high polarity level. The SPI interrupts are described as follows: †

- Transmit FIFO Empty Interrupt – Set when the transmit FIFO buffer is equal to or below its threshold value and requires service to prevent an underrun. The threshold value, set through a software-programmable register, determines the level of transmit FIFO buffer entries at which an interrupt is generated. This interrupt is cleared by hardware when data are written into the transmit FIFO buffer, bringing it over the threshold level. †
- Transmit FIFO Overflow Interrupt – Set when a master attempts to write data into the transmit FIFO buffer after it has been completely filled. When set, new data writes are discarded. This interrupt remains set until you read the transmit FIFO overflow interrupt clear register (`TXOICR`). †
- Receive FIFO Full Interrupt – Set when the receive FIFO buffer is equal to or above its threshold value plus 1 and requires service to prevent an overflow. The threshold value, set through a software-programmable register, determines the level of receive FIFO buffer entries at which an interrupt is generated. This interrupt is cleared by hardware when data are read from the receive FIFO buffer, bringing it below the threshold level. †
- Receive FIFO Overflow Interrupt – Set when the receive logic attempts to place data into the receive FIFO buffer after it has been completely filled. When set, newly received data are discarded. This interrupt remains set until you read the receive FIFO overflow interrupt clear register (`RXOICR`). †
- Receive FIFO Underflow Interrupt – Set when a system bus access attempts to read from the receive FIFO buffer when it is empty. When set, zeros are read back from the receive FIFO buffer. This interrupt remains set until you read the receive FIFO underflow interrupt clear register (`RXUICR`). †
- Combined Interrupt Request – ORed result of all the above interrupt requests after masking. To mask this interrupt signal, you must mask all other SPI interrupt requests. †

Transmit FIFO Overflow, Transmit FIFO Empty, Receive FIFO Full, Receive FIFO Underflow, and Receive FIFO Overflow interrupts can all be masked independently, using the Interrupt Mask Register (`IMR`). †

Interface Pins

Table 19-2: Interface Pins

Signal Name	Signal Width	Direction	Description
	SPI Master		

Signal Name	Signal Width	Direction	Description
CLK	1	Out	Serial clock output from the SPI master
MOSI	1	Out	Transmit data line for the SPI master
MISO	1	In	Receive data line for the SPI master
SS0	1	Out	Slave Select 0 Slave select signal from SPI master
SS1	1	Out	Slave Select 1 Slave select signal from SPI master
	SPI Slave		
CLK	1	In	Serial clock input to the SPI slave
MOSI	1	Out	Receive data line for the SPI slave

spis_ss_in_n	1	Out	Master Contention Input
spis_ssi_oe_n	1	Out	Output enable for the SPI slave
spis_sclk_in	1	In	Serial clock input

Transfer Modes

When transferring data on the serial bus, the SPI controller operates one of several modes. The transfer mode (TMOD) is set by writing to control register 0 (`CTRLR0`).

Note: The transfer mode setting does not affect the duplex of the serial transfer. TMOD is ignored for Microwire transfers, which are controlled by the MWCR register. †

Transmit and Receive

When TMOD = 0, both transmit and receive logic are valid. The data transfer occurs as normal according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO buffer and sent through the `txd` line to the target device, which replies with data on the `rxd` line. The receive data from the target device is moved from the receive shift register into the receive FIFO buffer at the end of each data frame. †

Transmit Only

When TMOD = 1, any receive data are ignored. The data transfer occurs as normal, according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO buffer and sent through the `txd` line to the target device, which replies with data on the `rxd` line. At the end of the data frame, the receive shift register does not load its newly received data into the receive FIFO buffer. The data in the receive shift register is overwritten by the next transfer. You should mask interrupts originating from the receive logic when this mode is entered. †

Receive Only

When TMOD = 2, the transmit data are invalid. In the case of the SPI slave, the transmit FIFO buffer is never popped in Receive Only mode. The `txd` output remains at a constant logic level during the transmission. The data transfer occurs as normal according to the selected frame format (serial protocol). The receive data from the target device is moved from the receive shift register into the receive FIFO buffer at the end of each data frame. You should mask interrupts originating from the transmit logic when this mode is entered. †

EEPROM Read

Note: This transfer mode is only valid for serial masters. †

When TMOD = 3, the transmit data is used to transmit an opcode and/or an address to the EEPROM device. This takes three data frames (8-bit opcode followed by 8-bit upper address and 8-bit lower address). During the transmission of the opcode and address, no data is captured by the receive logic (as long as the SPI master is transmitting data on its `txd` line, data on the `rxd` line is ignored). The SPI master continues to transmit data until the transmit FIFO buffer is empty. You should ONLY have enough data frames in the transmit FIFO buffer to supply the opcode and address to the EEPROM. If more data frames are in the transmit FIFO buffer than are needed, then Read data is lost. †

When the transmit FIFO buffer becomes empty (all control information has been sent), data on the receive line (`rxd`) is valid and is stored in the receive FIFO buffer; the `txd` output is held at a constant logic level. The serial transfer continues until the number of data frames received by the SPI master matches the value of the NDF field in the `CTRLR1` register plus one. †

Note: EEPROM read mode is not supported when the SPI controller is configured to be in the SSP mode. †

SPI Master

The SPI master initiates and controls all serial transfers with serial-slave peripheral devices. †

The serial bit-rate clock, generated and controlled by the SPI controller, is driven out on the `sclk_out` line. When the SPI controller is disabled, no serial transfers can occur and `sclk_out` is held in “inactive” state, as defined by the serial protocol under which it operates. †

Related Information

SPI Block Diagram on page 19-2

RXD Sample Delay

The SPI master device is capable of delaying the default sample time of the `rxd` signal in order to increase the maximum achievable frequency on the serial bus.

Round trip routing delays on the sclk_out signal from the master and the rxd signal from the slave can mean that the timing of the rxd signal, as seen by the master, has moved away from the normal sampling time.

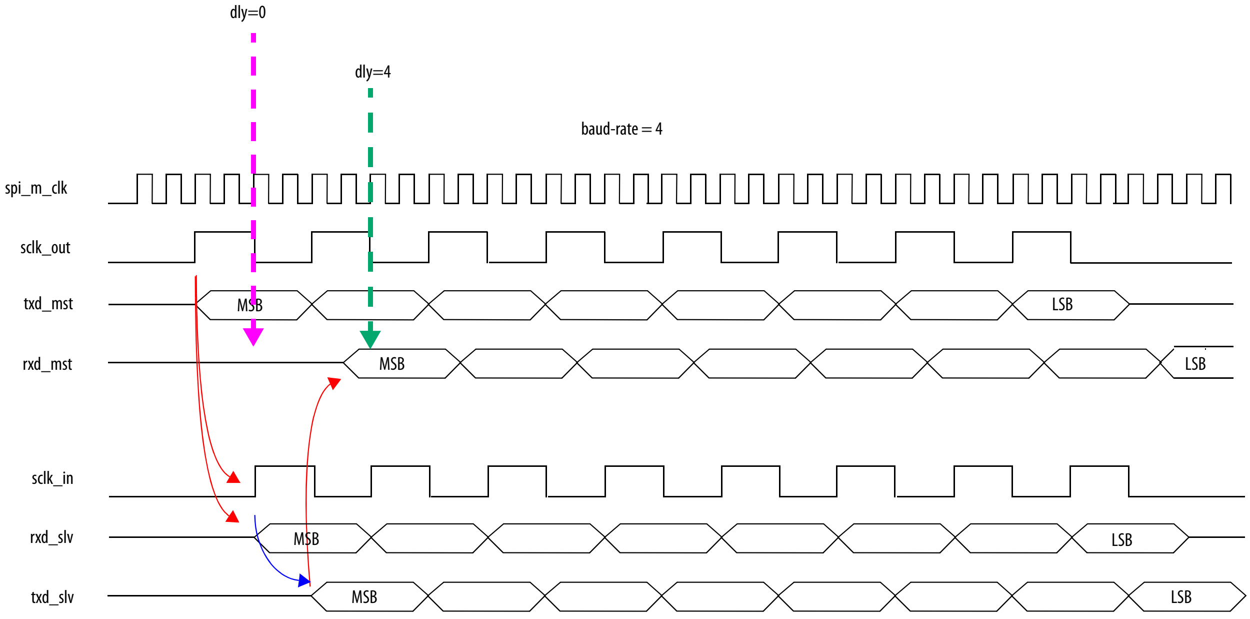
Without the RXD sample delay, you must increase the baud rate for the transfer in order to ensure that the setup times on the rxd signal are within range. This reduces the frequency of the serial interface.

Additional logic is included in the SPI master to delay the default sample time of the rxd signal. This additional logic can help to increase the maximum achievable frequency on the serial bus. †

By writing to the rsd field of the RX Sample Delay Register (rx_sample_dly), you specify an additional amount of delay applied to the rxd sample, in number of l4_main_clk clock cycles, up to 64 cycles. If the rsd field is programmed with a value exceeding 64, zero delay is applied to the rxd sample.

Round trip routing delays on the sclk_out signal from the master and the rxd signal from the slave can mean that the timing of the rxd signal, as seen by the master, has moved away from the normal sampling time. Red arrows indicate routing delay between master and slave devices. Blue arrow indicates sampling delay within slave from receiving sclk_in to driving txd out. †

Figure 19-4: Effects of Round Trip Routing Delays on sclk_out Signal



Red arrows indicate routing dela   y between master and slave devices
Blue arrow indicates sampling delay within slav   e from receiving slk_in to driving txd out

Data Transfers

The SPI master starts data transfers when all the following conditions are met:

- The SPI master is enabled
- There is at least one valid entry in the transmit FIFO buffer
- A slave device is selected

When actively transferring data, the busy flag (BUSY) in the status register (SR) is set. You must wait until the busy flag is cleared before attempting a new serial transfer. †

Note: The BUSY status is not set when the data are written into the transmit FIFO buffer. This bit gets set only when the target slave has been selected and the transfer is underway. After writing data into the transmit FIFO buffer, the shift logic does not begin the serial transfer until a positive edge of the sclk_out signal is present. The delay in waiting for this positive edge depends on the baud rate of the serial transfer. Before polling the BUSY status, you should first poll the Transit FIFO Empty (TFE) status (waiting for 1) or wait for (BAUDR * SPI clock) clock cycles. †

Master SPI and SSP Serial Transfers

"Motorola SPI Protocol" and "Texas Instruments Synchronous Serial Protocol (SSP)" describe the SPI and SSP serial protocols, respectively. †

When the transfer mode is "transmit and receive" or "transmit only" (TMOD = 0 or TMOD = 1, respectively), transfers are terminated by the shift control logic when the transmit FIFO buffer is empty. For continuous data transfers, you must ensure that the transmit FIFO buffer does not become empty before all the data have been transmitted. The transmit FIFO threshold level (TXFTLR) can be used to early interrupt (Transmit FIFO Empty Interrupt) the processor indicating that the transmit FIFO buffer is nearly empty. †

When the DMA is used in conjunction with the SPI master, the transmit data level (DMATDLR) can be used to early request the DMA Controller, indicating that the transmit FIFO buffer is nearly empty. The FIFO buffer can then be refilled with data to continue the serial transfer. The user may also write a block of data (at least two FIFO buffer entries) into the transmit FIFO buffer before enabling a serial slave. This ensures that serial transmission does not begin until the number of data frames that make up the continuous transfer are present in the transmit FIFO buffer. †

When the transfer mode is "receive only" (TMOD = 2), a serial transfer is started by writing one "dummy" data word into the transmit FIFO buffer when a serial slave is selected. The txd output from the SPI controller is held at a constant logic level for the duration of the serial transfer. The transmit FIFO buffer is popped only once at the beginning and may remain empty for the duration of the serial transfer. The end of the serial transfer is controlled by the "number of data frames" (NDF) field in control register 1 (CTRLR1). †

If, for example, you want to receive 24 data frames from a serial-slave peripheral, you should program the NDF field with the value 23; the receive logic terminates the serial transfer when the number of frames received is equal to the NDF value plus one. This transfer mode increases the bandwidth of the system bus as the transmit FIFO buffer never needs to be serviced during the transfer. The receive FIFO buffer should be read each time the receive FIFO buffer generates a FIFO full interrupt request to prevent an overflow. †

When the transfer mode is "eeprom_read" (TMOD = 3), a serial transfer is started by writing the opcode and/or address into the transmit FIFO buffer when a serial slave (EEPROM) is selected. The opcode and address are transmitted to the EEPROM device, after which read data is received from the EEPROM device and stored in the receive FIFO buffer. The end of the serial transfer is controlled by the NDF field in the control register 1 (CTRLR1). †

Note: EEPROM read mode is not supported when the SPI controller is configured to be in the SSP mode. †

The receive FIFO threshold level (RXF TLR) can be used to give early indication that the receive FIFO buffer is nearly full. When a DMA is used, the receive data level (DMARDLR) can be used to early request the DMA Controller, indicating that the receive FIFO buffer is nearly full. †

Master Microwire Serial Transfers

“National Semiconductor Microwire Protocol” describes the Microwire serial protocol in detail. †

Microwire serial transfers from the SPI serial master are controlled by the Microwire Control Register (MWCR). The MHS bit field enables and disables the Microwire handshaking interface. The MDD bit field controls the direction of the data frame (the control frame is always transmitted by the master and received by the slave). The MWMOD bit field defines whether the transfer is sequential or nonsequential. †

All Microwire transfers are started by the SPI serial master when there is at least one control word in the transmit FIFO buffer and a slave is enabled. When the SPI master transmits the data frame (MDD =1), the transfer is terminated by the shift logic when the transmit FIFO buffer is empty. When the SPI master receives the data frame (MDD = 1), the termination of the transfer depends on the setting of the MWMOD bit field. If the transfer is nonsequential (MWMOD = 0), it is terminated when the transmit FIFO buffer is empty after shifting in the data frame from the slave. When the transfer is sequential (MWMOD = 1), it is terminated by the shift logic when the number of data frames received is equal to the value in the CTRLR1 register plus one. †

When the handshaking interface on the SPI master is enabled (MHS =1), the status of the target slave is polled after transmission. Only when the slave reports a *ready status* does the SPI master complete the transfer and clear its BUSY status. If the transfer is continuous, the next control/data frame is not sent until the slave device returns a *ready status*. †

SPI Slave

The SPI slave handles serial communication with transfer initiated and controlled by serial master peripheral devices.

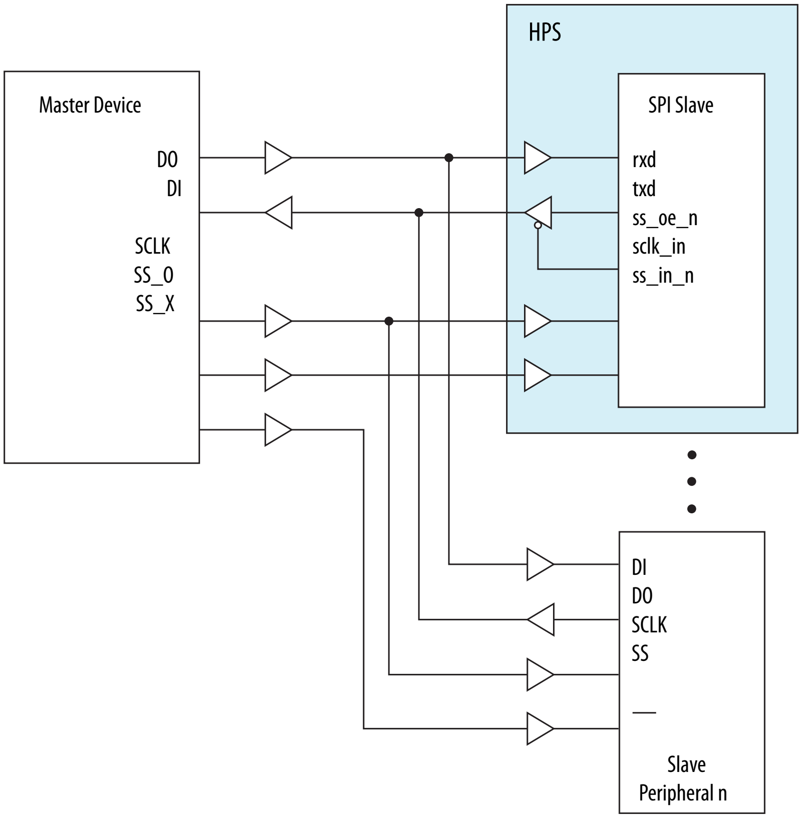
- sclk_in—serial clock to the SPI slave †
- ss_in_n—slave select input to the SPI slave †
- ss_oe_n—output enable for the SPI master or slave †
- txd—transmit data line for the SPI master or slave †
- rxd—receive data line for the SPI master or slave †

When the SPI serial slave is selected, it enables its txd data onto the serial bus. All data transfers to and from the serial slave are regulated on the serial clock line (sclk_in), driven from the SPI master device. Data are propagated from the serial slave on one edge of the serial clock line and sampled on the opposite edge. †

When the SPI serial slave is not selected, it must not interfere with data transfers between the serial-master and other serial-slave devices. When the serial slave is not selected, its txd output is buffered, resulting in a high impedance drive onto the SPI master rxd line. The buffers shown in the SPI Slave diagram are external to SPI controller. spi_oe_n is the SPI slave output enable signal. †

The serial clock that regulates the data transfer is generated by the serial-master device and input to the SPI slave on sclk_in. The slave remains in an idle state until selected by the bus master. When not actively transmitting data, the slave must hold its txd line in a high impedance state to avoid interference with serial transfers to other slave devices. The SPI slave output enable (ss_oe_n) signal is available for use to control the txd output buffer. The slave continues to transfer data to and from the master device as long as it is selected. If the master transmits to all serial slaves, a control bit (SLV_OE) in the SPI control register 0 (CTRLR0) can be programmed to inform the slave if it should respond with data from its txd line. †

Figure 19-5: SPI Slave



Slave SPI and SSP Serial Transfers †

“Motorola SPI Protocol” and the “Texas Instruments Synchronous Serial Protocol (SSP)” contain a description of the SPI and SSP serial protocols, respectively. †

If the SPI slave is *receive only* (TMOD=2), the transmit FIFO buffer need not contain valid data because the data currently in the transmit shift register is resent each time the slave device is selected. The TXE error flag in the status register (SR) is not set when TMOD=2. You should mask the Transmit FIFO Empty Interrupt when this mode is used. †

If the SPI slave transmits data to the master, you must ensure that data exists in the transmit FIFO buffer before a transfer is initiated by the serial-master device. If the master initiates a transfer to the SPI slave when no data exists in the transmit FIFO buffer, an error flag (TXE) is set in the SPI status register, and the previously transmitted data frame is resent on txd. For continuous data transfers, you must ensure that the transmit FIFO buffer does not become empty before all the data have been transmitted. The transmit FIFO threshold level register (TXFTLR) can be used to early interrupt (Transmit FIFO Empty Interrupt) the processor, indicating that the transmit FIFO buffer is nearly empty. When a DMA Controller is used, the DMA transmit data level register (DMATDLR) can be used to early request the DMA Controller, indicating that the transmit FIFO buffer is nearly empty. The FIFO buffer can then be refilled with data to continue the serial transfer. †

The receive FIFO buffer should be read each time the receive FIFO buffer generates a FIFO full interrupt request to prevent an overflow. The receive FIFO threshold level register (RXFTLR) can be used to give early indication that the receive FIFO buffer is nearly full. When a DMA Controller is used, the DMA receive data level register (DMARDLR) can be used to early request the DMA controller, indicating that the receive FIFO buffer is nearly full. †

Serial Transfers

“National Semiconductor Microwire Protocol” describes the Microwire serial protocol in detail, including timing diagrams and information about how data are structured in the transmit and receive FIFO buffers before and after a serial transfer. The Microwire protocol operates in much the same way as the SPI protocol. There is no decode of the control frame by the SPI slave device. †

Related Information

National Semiconductor Microwire Protocol on page 19-17

Glue Logic for Master Port ss_in_n

When configured as a master, the SPI has an input, ssi_in_n, which can be used by the deciding logic in a multi-master system to disable one master when another has priority. The polarity of this signal depends on the serial protocol in use, and the protocol is dynamically selectable.

The table below lists the three protocols and the effect of ss_in_n on the ability of the master to transfer data. Note that for the SSP protocol the effect of ss_in_n is inverted with respect to the other protocols.

Protocol	ss_in_n value	Effect on Serial Transfer
Motorola SPI	1	Enabled
	0	Disabled
National Semiconductor Microwire	1	Enabled
	0	Disabled
Texas Instruments Serial Protocol (SSP)	1	Disabled
	0	Enabled

Partner Connection Interfaces

The SPI can connect to any serial-master or serial-slave peripheral device using one of several interfaces.

Motorola SPI Protocol

The inactive state of the serial clock is low. The data frame can be 4 to 16 bits in length. †

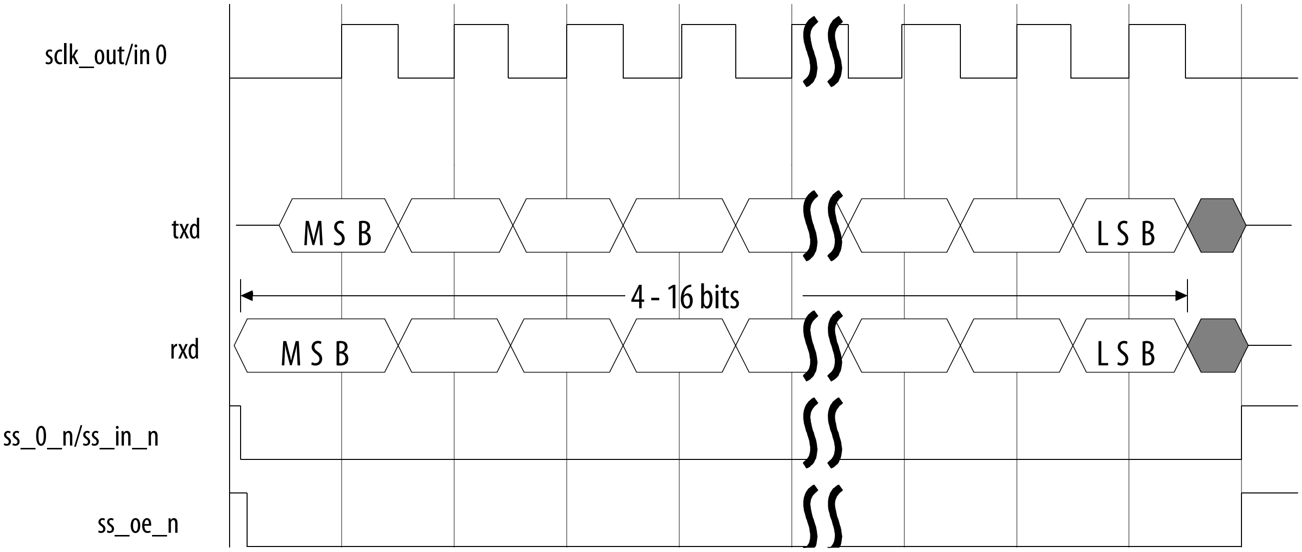
Data transmission begins on the falling edge of the slave select signal. The first data bit is captured by the master and slave peripherals on the first edge of the serial clock; therefore, valid data must be present on the txd and rxd lines prior to the first serial clock edge. †

The slave select signal takes effect only when used as slave SPI. For master SPI, the data transmission begins as soon as the output enable signal is deasserted.

The following signals are illustrated in the timing diagrams in this section: †

- `sclk_out`—serial clock from SPI master †
- `sclk_in`—serial clock from SPI slave †
- `ss_0_n`—slave select signal from SPI master †
- `ss_oe_n`—output enable for the SPI master or slave †
- `txd`—transmit data line for the SPI master or slave †
- `rxd`—receive data line for the SPI master or slave †

Figure 19-6: SPI Serial Format



There are four possible transfer modes on the SPI controller for performing SPI serial transactions; refer to “Transfer Modes” . For *transmit and receive transfers* (transfer mode field (9:8) of the Control Register 0 = 0), data transmitted from the SPI controller to the external serial device is written into the transmit FIFO buffer. Data received from the external serial device into the SPI controller is pushed into the receive FIFO buffer. †

Note: For *transmit only* transfers (transfer mode field (9:8) of the Control Register 0 = 1), data transmitted from the SPI controller to the external serial device is written into the transmit FIFO buffer. As the data received from the external serial device is deemed invalid, it is not stored in the SPI receive FIFO buffer. †

For *receive only* transfers (transfer mode field (9:8) of the Control Register 0 = 2), data transmitted from the SPI controller to the external serial device is invalid, so a single dummy word is written into the transmit FIFO buffer to begin the serial transfer. The `txd` output from the SPI controller is held at a constant logic level for the duration of the serial transfer. Data received from the external serial device into the SPI controller is pushed into the receive FIFO buffer. †

For eeprom_read transfers (transfer mode field [9:8] of the Control Register 0 = 3), opcode and/or EEPROM address are written into the transmit FIFO buffer. During transmission of these control frames, received data is not captured by the SPI master. After the control frames have been transmitted, receive data from the EEPROM is stored in the receive FIFO buffer.

SPI Serial Format

Two different modes of continuous data transfers are supported when `SCPH` = 0 and 1.†

- When the clock phase, SCPH = 0, the SPI Controller toggles the slave select signal between frames and the serial clock is held to its default value while the slave select signal is active.†
- When SCPH = 1, the slave select is held active for the duration of the transfer.†

Figure 19-7: Serial Format Continuous Transfers (SCPH =0)

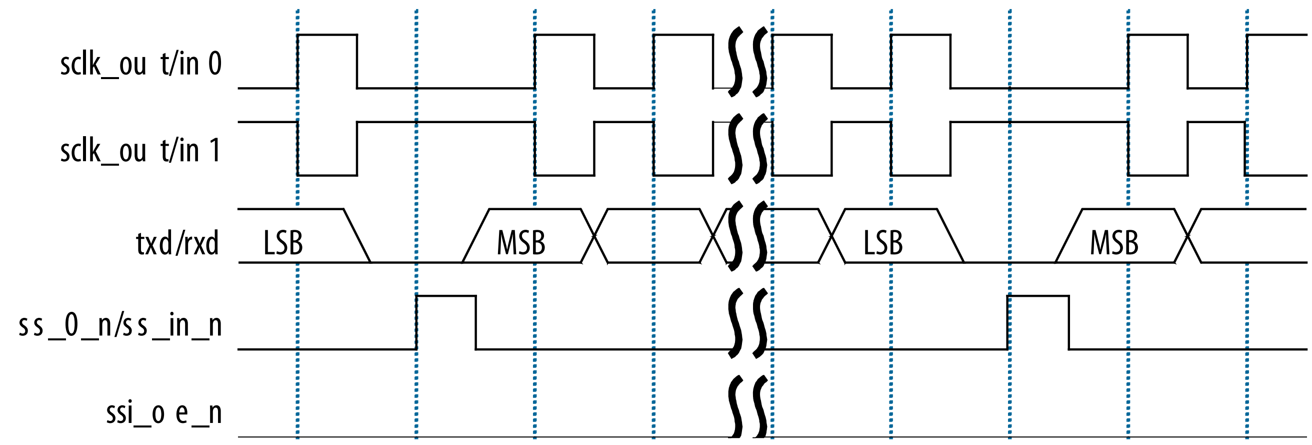


Figure 19-8: Serial Format Continuous Transfers (SCPH =1)

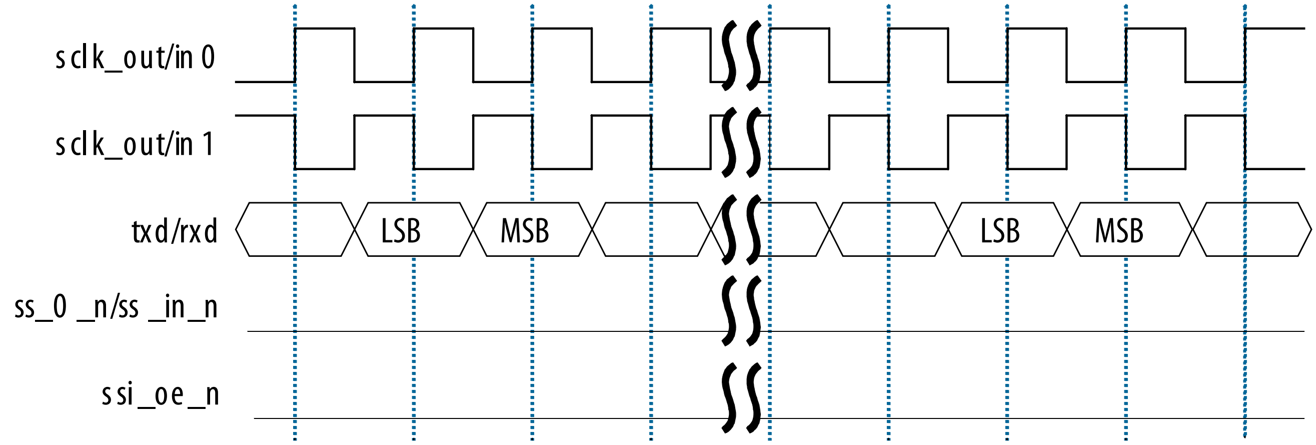


Related Information

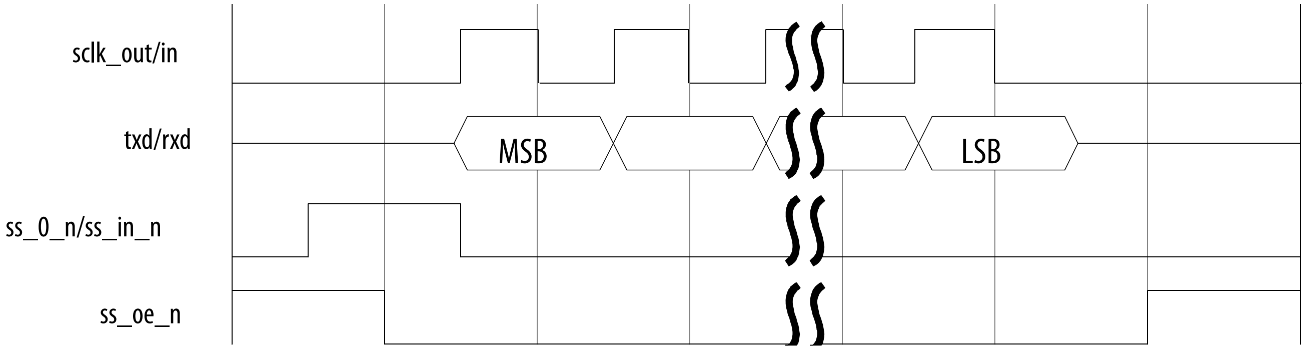
Transfer Modes on page 19-8

Texas Instruments Synchronous Serial Protocol (SSP)

Data transfers begin by asserting the frame indicator line (`ss_0_n`) for one serial clock period. Data to be transmitted are driven onto the `txd` line one serial clock cycle later; similarly data from the slave are driven onto the `rxd` line. Data are propagated on the rising edge of the serial clock (`sclk_out/sclk_in`) and captured on the falling edge. The length of the data frame ranges from 4 to 16 bits.

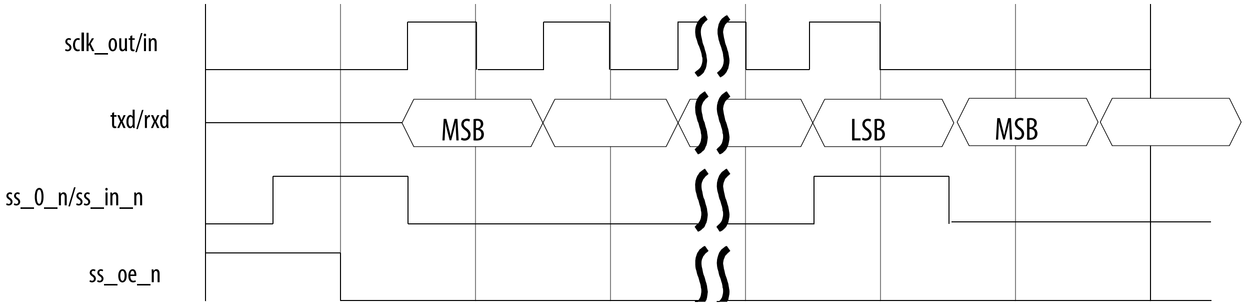
Note: The slave select signal (`ss_0_n`) takes effect only when used as slave SPI. For master SPI, the data transmission begins as soon as the output enable signal is deasserted.

Figure 19-9: SSP Serial Format



Continuous data frames are transferred in the same way as single data frames. The frame indicator is asserted for one clock period during the same cycle as the LSB from the current transfer, indicating that another data frame follows. †

Figure 19-10: SSP Serial Format Continuous Transfer



National Semiconductor Microwire Protocol

For the master SPI, data transmission begins as soon as the output enable signal is deasserted. One-half serial clock (`sclk_out`) period later, the first bit of the control is sent out on the `txd` line. The length of the control word can be in the range 1 to 16 bits and is set by writing bit field CFS (bits 15:12) in `CTRLR0`. The remainder of the control word is transmitted (propagated on the falling edge of `sclk_ou t`) by the SPI serial master. During this transmission, no data are present (high impedance) on the serial master's `rxd` line. †

The direction of the data word is controlled by the MDD bit field (bit 1) in the Microwire Control Register (`MWCR`). When MDD=0, this indicates that the SPI serial master receives data from the external serial slave. One clock cycle after the LSB of the control word is transmitted, the slave peripheral responds with a dummy 0 bit, followed by the data frame, which can be 4 to 16 bits in length. Data are propagated on the falling edge of the serial clock and captured on the rising edge. †

Continuous transfers from the Microwire protocol can be sequential or nonsequential, and are controlled by the MWMOD bit field (bit 0) in the MWCR. †

Nonsequential continuous transfers occur, with the control word for the next transfer following immediately after the LSB of the current data word. †

The only modification needed to perform a continuous nonsequential transfer is to write more control words into the transmit FIFO buffer. †

During sequential continuous transfers, only one control word is transmitted from the SPI master. The transfer is started in the same manner as with nonsequential read operations, but the cycle is continued to read further data. The slave device automatically increments its address pointer to the next location and continues to provide data from that location. Any number of locations can be read in this manner; the SPI master terminates the transfer when the number of words received is equal to the value in the `CTRLR1` register plus one. †

When MDD = 1, this indicates that the SPI serial master transmits data to the external serial slave. Immediately after the LSB of the control word is transmitted, the SPI master begins transmitting the data frame to the slave peripheral. †

Note: The SPI controller does not support continuous sequential Microwire writes, where MDD = 1 and MWMOD = 1. †

Continuous transfers occur with the control word for the next transfer following immediately after the LSB of the current data word.

The Microwire handshaking interface can also be enabled for SPI master write operations to external serial-slave devices. To enable the handshaking interface, you must write 1 into the MHS bit field (bit 2) on the MWCR register. When MHS is set to 1, the SPI serial master checks for a ready status from the slave device before completing the transfer, or transmitting the next control word for continuous transfers. †

After the first data word has been transmitted to the serial-slave device, the SPI master polls the `rxd` input waiting for a ready status from the slave device. Upon reception of the ready status, the SPI master begins transmission of the next control word. After transmission of the last data frame has completed, the SPI master transmits a start bit to clear the ready status of the slave device before completing the transfer. †

In the SPI slave, data transmission begins with the falling edge of the slave select signal (`ss_in_0`). One-half serial clock (`sclk_in`) period later, the first bit of the control is present on the `rxd` line. The length of the control word can be in the range of 1 to 16 bits and is set by writing bit field CFS in the `CTRLR0` register. The CFS bit field must be set to the size of the expected control word from the serial master. The remainder of the control word is received (captured on the rising edge of `sclk_in`) by the SPI serial slave. During this reception, no data are driven (high impedance) on the serial slave's `txd` line. †

The direction of the data word is controlled by the MDD bit field (bit 1) MWCR register. When MDD=0, this indicates that the SPI serial slave is to receive data from the external serial master. Immediately after the control word is transmitted, the serial master begins to drive the data frame onto the SPI slave `rxd` line. Data are propagated on the falling edge of the serial clock and captured on the rising edge. The slave-select signal is held active-low during the transfer and is deasserted one-half clock cycle later after the data are transferred. The SPI slave output enable signal is held inactive for the duration of the transfer. †

When MDD=1, this indicates that the SPI serial slave transmits data to the external serial master. Immediately after the LSB of the control word is transmitted, the SPI slave transmits a dummy 0 bit, followed by the 4- to 16-bit data frame on the `txd` line. †

Continuous transfers for a SPI slave occur in the same way as those specified for the SPI master. The SPI slave does not support the handshaking interface, as there is never a busy period. †

Figure 19-11: Single SPI Serial Master Microwire Serial Transfer (MDD=0)

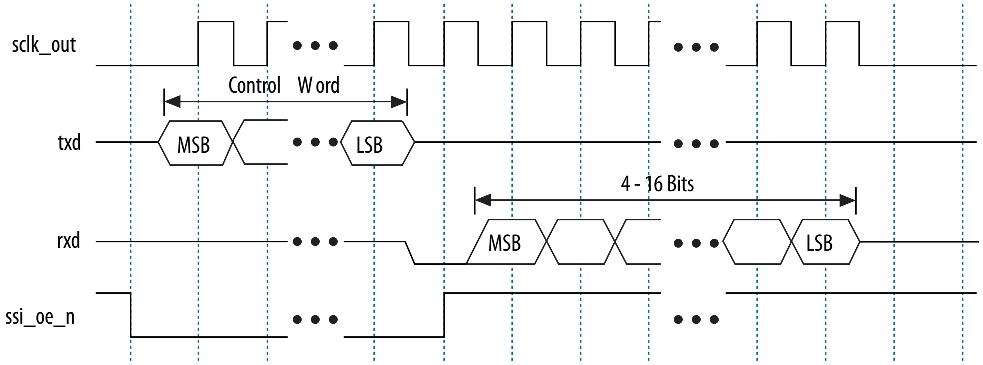


Figure 19-12: Single SPI Slave Microwire Serial Transfer (MDD=1)

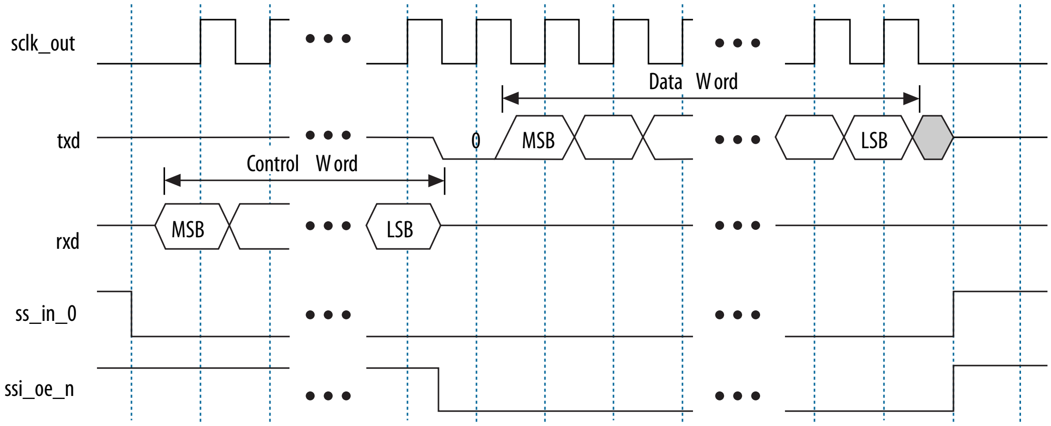


DMA Controller Interface

The SPI controller supports DMA signaling to indicate when the receive FIFO buffer has data ready to be read or when the transmit FIFO buffer needs data. It requires two DMA channels, one for transmit data and one for receive data. The SPI controller can issue single or burst DMA transfers and accepts burst acknowledges from the DMA. System software can trigger the DMA burst mode by programming an appropriate value into the threshold registers. The typical setting of the threshold register value is half full.

To enable the DMA Controller interface on the SPI controller, you must write the DMA Control Register (DMACR). Writing a 1 into the TDMAE bit field of DMACR register enables the SPI transmit handshaking interface. Writing a 1 into the RDMAE bit field of the DMACR register enables the SPI receive handshaking interface. †

Slave Interface

The host processor accesses data, control, and status information about the SPI controller through the slave interface. The SPI supports a data bus width of 32 bits.

Control and Status Register Access

Control and status registers within the SPI controller are byte-addressable. The maximum width of the control or status register in the SPI controller is 16 bits. Therefore, all read and write operations to the SPI control and status registers require only one access. †

Data Register Access

The data register (DR) within the SPI controller is 16 bits wide in order to remain consistent with the maximum serial transfer size (data frame). A write operation to DR moves data from the slave write data bus into the transmit FIFO buffer. An read operation from DR moves data from the receive FIFO buffer onto the slave readback data bus. †

Note: The DR register in the SPI controller occupies sixty-four 32-bit locations of the memory map to facilitate burst transfers. There are no burst transactions on the system bus itself, but SPI supports bursts on the system interconnect. Writing to any of these address locations has the same effect as pushing the data from the slave write data bus into the transmit FIFO buffer. Reading from any of these locations has the same effect as popping data from the receive FIFO buffer onto the slave readback data bus. The FIFO buffers on the SPI controller are not addressable

Clocks and Resets

The SPI controller uses the clock and reset signals shown in the following table.

Table 19-5: SPI Controller Clocks and Resets

	Master	Slave
SPI clock	spi_m_clk	l4_main_clk
SPI bit-rate clock	sclk_out	sclk_in
Reset	spim_rst_n	spis_rst_n

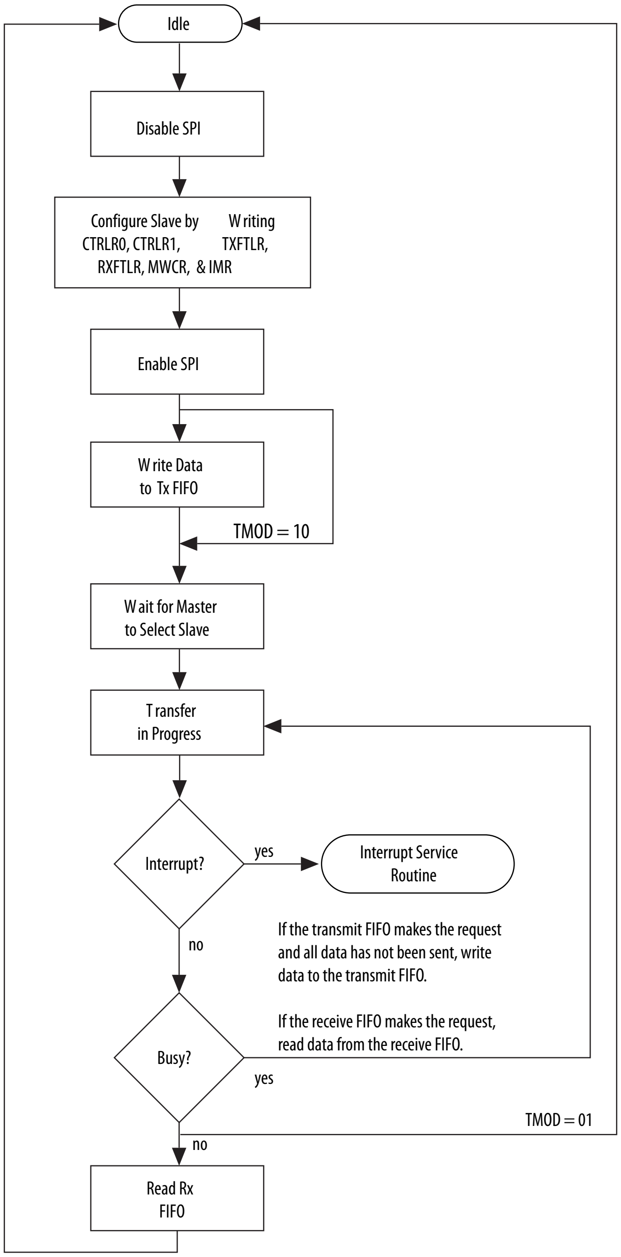
SPI Programming Model

This section describes the programming model for the SPI controller based on the following master and slave transfers:

- Master SPI and SSP serial transfers
- Master Microwire Serial Transfers
- Slave SPI and SSP Serial Transfers
- Slave Microwire Serial Transfers
- Software Control for Slave Selection

Master SPI and SSP Serial Transfers

Figure 19-13: Master SPI or SSP Serial Transfer Software Flow



Idle
Disable SPI
Configure Slave by Writing CTRLR0, CTRLR1, TXFTLR, RXFTLR, MWCR, & IMR
Enable SPI
Write Data to Tx FIFO
TMOD = 10
Wait for Master to Select Slave
Transfer in Progress
Interrupt?
yes
Interrupt Service Routine
no
If the transmit FIFO makes the request and all data has not been sent, write data to the transmit FIFO.
If the receive FIFO makes the request, read data from the receive FIFO.
Busy?
yes
TMOD = 01
no
Read Rx FIFO

To complete an SPI or SSP serial transfer from the SPI master, follow these steps:

1. If the SPI master is enabled, disable it by writing 0 to the SSI Enable register (`SSIENR`).
2. Set up the SPI master control registers for the transfer. You can set these registers in any order.

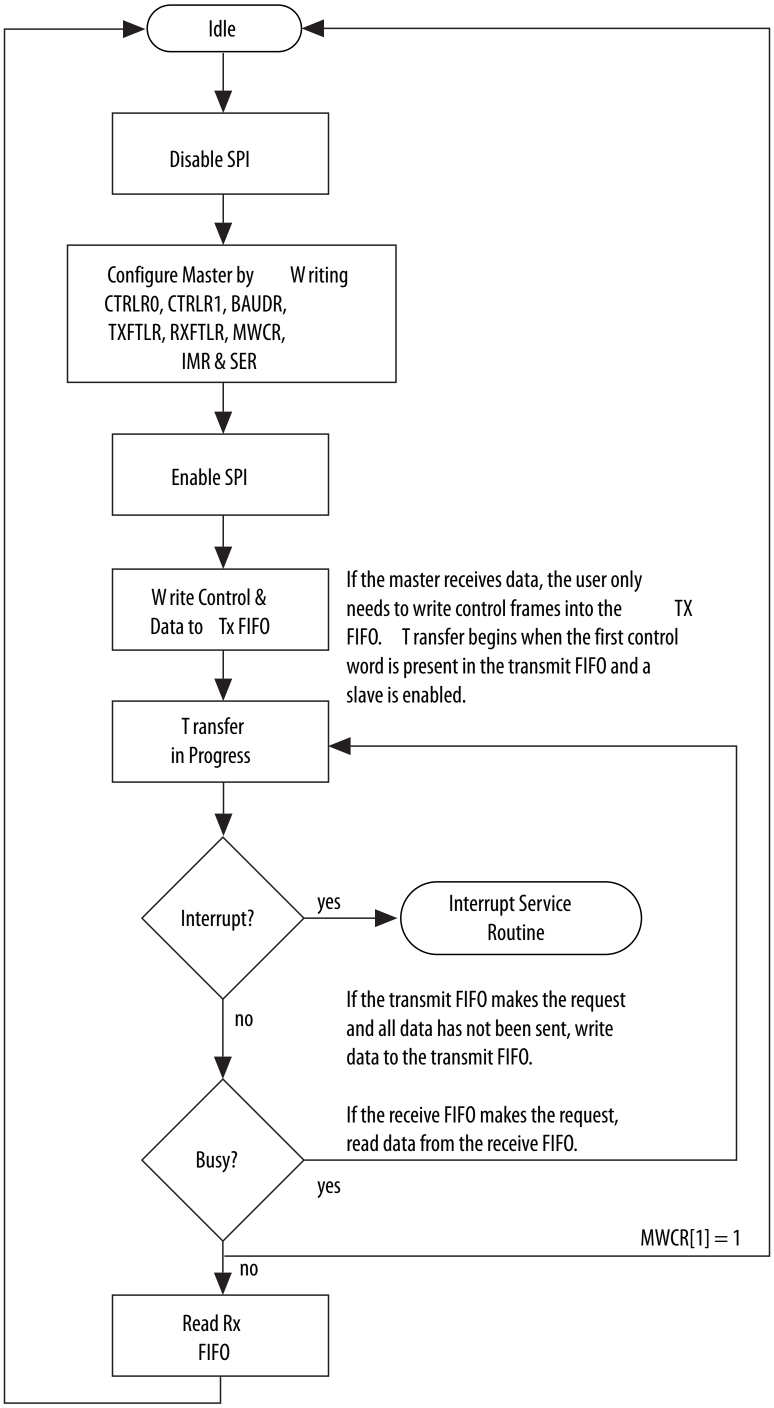
- Write Control Register 0 (`CTRLLR0`). For SPI transfers, you must set the serial clock polarity and serial clock phase parameters identical to the target slave device.
- If the transfer mode is receive only, write Control Register 1 (`CTRLR1`) with the number of frames in the transfer minus 1. For example, if you want to receive four data frames, write 3 to this register.
- Write the Baud Rate Select Register (`BAUDR`) to set the baud rate for the transfer.
- Write the Transmit and Receive FIFO Threshold Level registers (`TXFTLR` and `RXFTLR`) to set FIFO buffer threshold levels.
- Write the `IMR` register to set up interrupt masks.
- Write the Slave Enable Register (`SER`) register to enable the target slave for selection. If a slave is enabled at this time, the transfer begins as soon as one valid data entry is present in the transmit FIFO buffer. If no slaves are enabled prior to writing to the Data Register (`DR`), the transfer does not begin until a slave is enabled.

3. Enable the SPI master by writing 1 to the `SSIENR` register.
4. Write data for transmission to the target slave into the transmit FIFO buffer (write `DR`). If no slaves were enabled in the SER register at this point, enable it now to begin the transfer.
5. Poll the `BUSY` status to wait for the transfer to complete. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write `DR`). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read `DR`).

6. The shift control logic stops the transfer when the transmit FIFO buffer is empty. If the transfer mode is receive only (TMOD = 2), the shift control logic stops the transfer when the specified number of frames have been received. When the transfer is done, the `BUSY` status is reset to 0.
7. If the transfer mode is not transmit only (TMOD is not equal to 1), read the receive FIFO buffer until it is empty
8. Disable the SPI master by writing 0 to `SSIENR`.

Master Microwire Serial Transfers

Figure 19-14: Microwire Serial



Idle
Disable SPI
Configure Master by Writing CTRLR0, CTRLR1, BAUDR, TXFTLR, RXFTLR, MWCR, IMR & SER
Enable SPI
Write Control & Data to Tx FIFO
If the master receives data, the user only needs to write control frames into the TX FIFO. Transfer begins when the first control word is present in the transmit FIFO and a slave is enabled.
Transfer in Progress
Interrupt?
yes
Interrupt Service Routine
no
If the transmit FIFO makes the request and all data has not been sent, write data to the transmit FIFO.
If the receive FIFO makes the request, read data from the receive FIFO.
Busy?
yes
MWCR[1] = 1
no
Read Rx FIFO

To complete a Microwire serial transfer from the SPI master, follow these steps:

1. If the SPI master is enabled, disable it by writing 0 to SSIENR.
2. Set up the SPI control registers for the transfer. You can set these registers in any order.
   - Write CTRLR0 to set transfer parameters. If the transfer is sequential and the SPI master receives data, write CTRLR1 with the number of frames in the transfer minus 1. For example, if you want to receive four data frames, write 3 to this register.
   - Write BAUDR to set the baud rate for the transfer.
   - Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
   - Write the IMR register to set up interrupt masks.

   You can write the SER register to enable the target slave for selection. If a slave is enabled here, the transfer begins as soon as one valid data entry is present in the transmit FIFO buffer. If no slaves are enabled prior to writing to the DR register, the transfer does not begin until a slave is enabled.
3. Enable the SPI master by writing 1 to the SSIENR register.
4. If the SPI master transmits data, write the control and data words into the transmit FIFO buffer (write DR). If the SPI master receives data, write the control word or words into the transmit FIFO buffer. If no slaves were enabled in the SER register at this point, enable now to begin the transfer.
5. Poll the BUSY status to wait for the transfer to complete. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write DR). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read DR).
6. The shift control logic stops the transfer when the transmit FIFO buffer is empty. If the transfer mode is sequential and the SPI master receives data, the shift control logic stops the transfer when the specified number of data frames is received. When the transfer is done, the BUSY status is reset to 0.
7. If the SPI master receives data, read the receive FIFO buffer until it is empty.
8. Disable the SPI master by writing 0 to SSIENR.

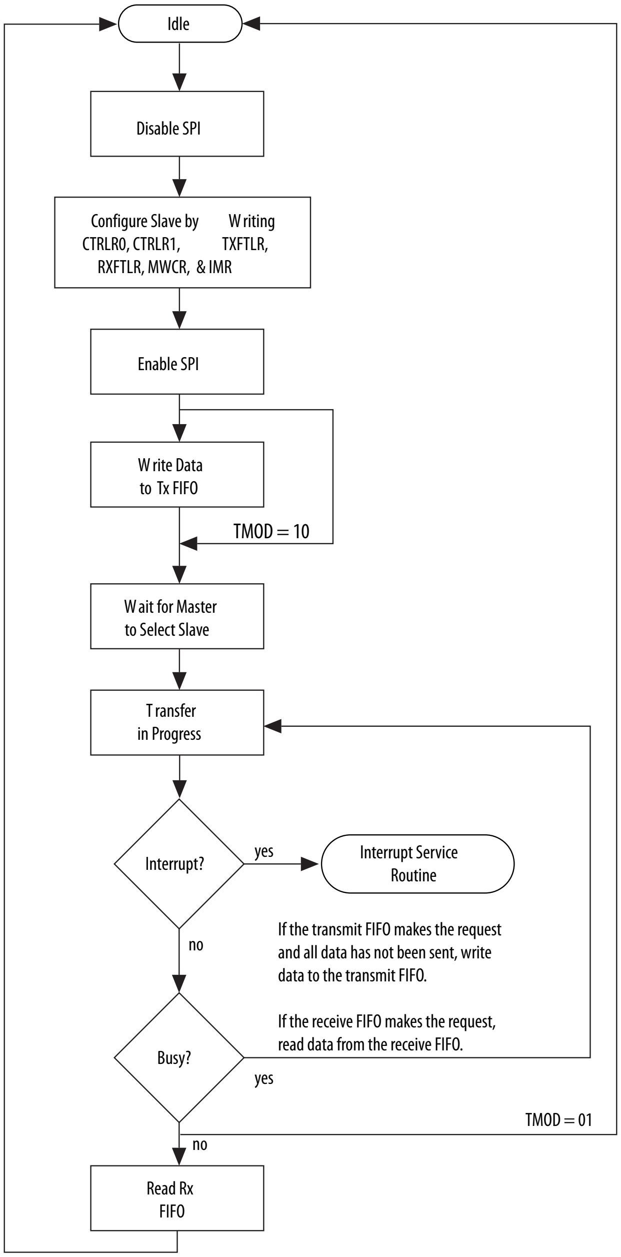
Slave SPI and SSP Serial Transfers

Figure 19-15: Slave SPI or SSP Serial Transfer Software Flow



Idle
Disable SPI
Configure Slave by Writing CTRLR0, CTRLR1, TXFTLR, RXFTLR, MWCR, & IMR
Enable SPI
Write Data to Tx FIFO
TMOD = 10
Wait for Master to Select Slave
Transfer in Progress
Interrupt?
yes
Interrupt Service Routine
no
If the transmit FIFO makes the request and all data has not been sent, write data to the transmit FIFO.
If the receive FIFO makes the request, read data from the receive FIFO.
Busy?
yes
TMOD = 01
no
Read Rx FIFO

To complete a continuous serial transfer from a serial master to the SPI slave, follow these steps:

1. If the SPI slave is enabled, disable it by writing 0 to `SSIENR`.
2. Set up the SPI control registers for the transfer. You can set these registers in any order.

- Write CTRLR0 (for SPI transfers, set SCPH and SCPOL identical to the master device).
- Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
- Write the IMR register to set up interrupt masks.

3. Enable the SPI slave by writing 1 to the SSIENR register.
4. If the transfer mode is transmit and receive (TMOD=2'b00) or transmit only (TMOD=2'b01), write data for transmission to the master into the transmit FIFO buffer (write DR). If the transfer mode is receive only (TMOD=2'b10), you need not write data into the transmit FIFO buffer. The current value in the transmit shift register is retransmitted.
5. The SPI slave is now ready for the serial transfer. The transfer begins when a serial-master device selects the SPI slave.
6. When the transfer is underway, the BUSY status can be polled to return the transfer status. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write DR). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read DR).
7. The transfer ends when the serial master removes the select input to the SPI slave. When the transfer is completed, the BUSY status is reset to 0.
8. If the transfer mode is not transmit only (TMOD != 01), read the receive FIFO buffer until empty.
9. Disable the SPI slave by writing 0 to SSIENR.

Slave Microwire Serial Transfers

For the SPI slave, the Microwire protocol operates in much the same way as the SPI protocol. The SPI slave does not decode the control frame.

Software Control for Slave Selection

When using software to select slave devices, the input select lines from serial slave devices is connected to a single slave select output on the SPI master.

Example: Slave Selection Software Flow for SPI Master

1. If the SPI master is enabled, disable it by writing 0 to SSIENR.
2. Write CTRLR0 to match the required transfer.
3. If the transfer is receive only, write the number of frames into CTRLR1.
4. Write BAUDR to set the transfer baud rate.
5. Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
6. Write IMR register to set interrupt masks.
7. Write SER register bit[0] to logic '1' to select slave 1 in this example.
8. Write SSIENR register bit[0] to logic '1' to enable SPI master.

Example: Slave Selection Software Flow for SPI Slave

1. If the SPI slave is enabled, disable it by writing 0 to SSIENR.
2. Write CTRLR0 to match the required transfer.
3. Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
4. Write IMR register to set interrupt masks.
5. Write SSIENR register bit[0] to logic '1' to enable SPI slave.
6. If the SPI slave transmits data, write data into TX FIFO buffer. Note all other SPI slaves are disabled (SSIENR = 0) and therefore will not respond to an active level on their ss_in_n port.

The FIFO buffer depth (FIFO_DEPTH) for both the RX and TX buffers in the SPI controller is 256 entries.

DMA Controller Operation

To enable the DMA controller interface on the SPI controller, you must write the DMA Control Register (DMACR). Writing a 1 to the TDMAE bit field of DMACR register enables the SPI controller transmit handshaking interface. Writing a 1 to the RDMAE bit field of the DMACR register enables the SPI controller receive handshaking.†

Related Information

DMA Controller on page 16-1
For details about the DMA controller, refer to the *DMA Controller* chapter.

Transmit FIFO Buffer Underflow

During SPI serial transfers, transmit FIFO buffer requests are made to the DMA Controller whenever the number of entries in the transmit FIFO buffer is less or equal to the value in DMA Transmit Data Level Register (DMATDLR); also known as the watermark level. The DMA Controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length.†

Note: Data should be fetched from the DMA often enough for the transmit FIFO buffer to perform serial transfers continuously, that is, when the FIFO buffer begins to empty, another DMA request should be triggered. Otherwise, the FIFO buffer will run out of data (underflow). To prevent this condition, you must set the watermark level correctly.†

Related Information

DMA Controller on page 16-1
For details about the DMA burst length microcode setup, refer to the *DMA Controller* chapter.

Transmit Watermark Level

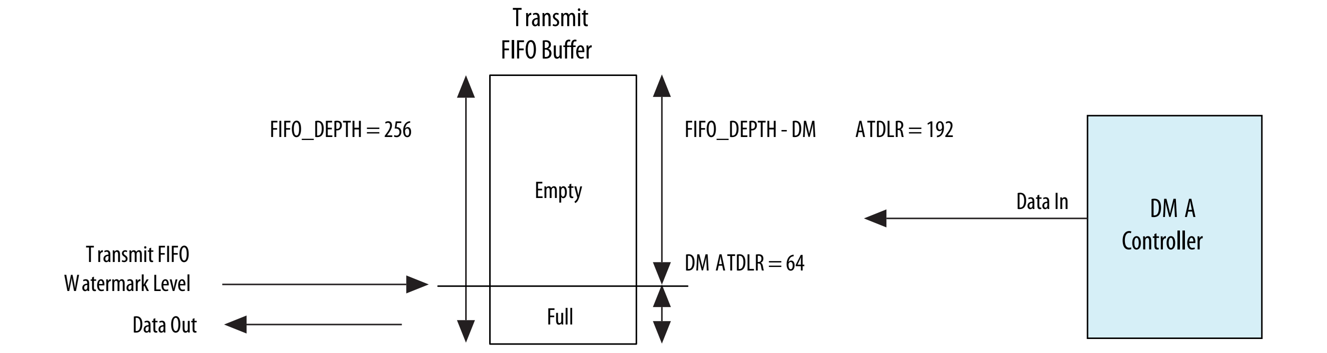
Consider the example where the assumption is made: †

DMA burst length = FIFO_DEPTH - DMATDLR

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO buffer. Consider the following two different watermark level settings. †

- Case 1: DMATDLR = 64: †
- Transmit FIFO watermark level = DMATDLR = 64: †
- DMA burst length = FIFO_DEPTH - DMATDLR = 192: †
- SPI transmit FIFO_DEPTH = 256: †
- Block transaction size = 960: †

Figure 19-16: Transmit FIFO Watermark Level = 64



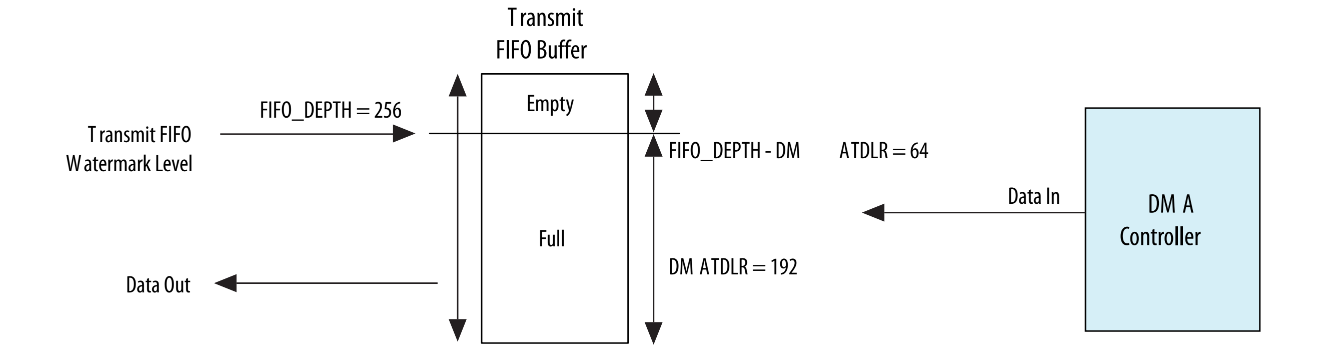
The number of burst transactions needed equals the block size divided by the number of data items per burst:

Block transaction size/DMA burst length = 960/192 = 5

The number of burst transactions in the DMA block transfer is 5. But the watermark level, DMATDLR, is quite low. Therefore, the probability of transmit underflow is high where the SPI serial transmit line needs to transmit data, but there is no data left in the transmit FIFO buffer. This occurs because the DMA has not had time to service the DMA request before the FIFO buffer becomes empty.

- Case 2: DMATDLR = 192†
- Transmit FIFO watermark level = D MATDLR = 192 †
- DMA burst length = FIFO_DEPTH - DMATDLR = 64 †
- SPI transmit FIFO_DEPTH = 256 †
- Block transaction size = 960 †

Figure 19-17: Transmit FIFO Watermark Level = 192



Number of burst transactions in block: †

Block transaction size/DMA burst length = 960/64 = 15 †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, DMATDLR, is high. Therefore, the probability of SPI transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the SPI transmit FIFO buffer becomes empty. †

Thus, the second case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case. †

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the SPI transmits data to the rate at which the DMA can respond to destination burst requests. †

Transmit FIFO Buffer Overflow

Setting the DMA transaction burst length to a value greater than the watermark level that triggers the DMA request may cause overflow when there is not enough space in the transmit FIFO buffer to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

DMA burst length <= `FIFO_DEPTH` - `DMATDLR`

In case 2: `DMATDLR` = 192, the amount of space in the transmit FIFO buffer at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO buffer may be full, but not overflowed, at the completion of the burst transaction. †

Therefore, for optimal operation, DMA burst length should be set at the FIFO buffer level that triggers a transmit DMA request; that is: †

DMA burst length = `FIFO_DEPTH` - `DMATDLR`

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO buffer will not be full at the end of a DMA burst transfer if the SPI controller has successfully transmitted one data item or more on the serial transmit line during the transfer. †

Receive FIFO Buffer Overflow

During SPI serial transfers, receive FIFO buffer requests are made to the DMA whenever the number of entries in the receive FIFO buffer is at or above the DMA Receive Data Level Register, that is `DMATDLR` + 1.This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO buffer. †

Data should be fetched by the DMA often enough for the receive FIFO buffer to accept serial transfers continuously, that is, when the FIFO buffer begins to fill, another DMA transfer is requested. Otherwise the FIFO buffer will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

Choosing Receive Watermark Level

Similar to choosing the transmit watermark level, the receive watermark level, `DMATDLR` + 1, should be set to minimize the probability of overflow. It is a trade off between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Related Information

Texas Instruments Synchronous Serial Protocol (SSP) on page 19-16

Receive FIFO Buffer Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

DMA burst length = `DMATDLR` + 1

If the number of data items in the receive FIFO buffer is equal to the source burst length at the time of the burst request is made, the receive FIFO buffer may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, `DMATDLR` + 1. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can improve bus utilization. †

Note: The receive FIFO buffer will not be empty at the end of the source burst transaction if the SPI controller has successfully received one data item or more on the serial receive line during the burst. †

ctrlr0 Fields

Bit	Name	Description	Access	Reset
15:12	cfs	Selects the length of the control word for the Microwire frame format. The length (in bits) is the value of this field plus 1.	RW	0x0
11	srl	Used for testing purposes only. When internally active, connects the transmit shift register output to the receive shift register input. **Value** **Description** 0x0 Normal Mode Operation 0x1 Test Mode Operation	RW	0x0

Bit	Name	Description	Access	Reset
9:8	`tmod`	Selects the mode of transfer for serial communication. This field does not affect the transfer duplicity. Only indicates whether the receive or transmit data are valid. In transmit-only mode, data received from the external device is not valid and is not stored in the receive FIFO memory. It is overwritten on the next transfer. In receive-only mode, transmitted data are not valid. After the first write to the transmit FIFO, the same word is retransmitted for the duration of the transfer. In transmit-and-receive mode, both transmit and receive data are valid. The transfer continues until the transmit FIFO is empty. Data received from the external device are stored into the receive FIFO memory, where it can be accessed by the host processor. **Value** **Description** 0x0 Transmit & and Receive 0x1 Transmit Only 0x2 Receive Only 0x3 EEPROM Read	`RW`	`0x0`
7	`scpol`	Valid when the frame format (FRF) is set to Motorola SPI. Used to select the polarity of the inactive serial clock, which is held inactive when the SPI Master is not actively transferring data on the serial bus. **Value** **Description** 0x0 Inactive state of serial clock is low 0x1 Inactive state of serial clock is high	`RW`	`0x0`
6	`scph`	Valid when the frame format (FRF) is set to Motorola SPI. The serial clock phase selects the relationship of the serial clock with the slave select signal. When SCPH = 0, data are captured on the first edge of the serial clock. When SCPH = 1, the serial clock starts toggling one cycle after the slave select line is activated, and data are captured on the second edge of the serial clock. **Value** **Description** 0x0 Serial clock toggles in middle of first data bit 0x1 Serial clock toggles at start of first data bit	`RW`	`0x0`

Bit	Name	Description	Access	Reset
5:4	`frf`	Selects which serial protocol transfers the data. **Value** — **Description** 0x0 — Motorola SPI 0x1 — Texas Instruments SSP 0x2 — National Semi Microwire	RW	0x0
3:0	`dfs`	Selects the data frame length. When the data frame size is programmed to be less than 16 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You must right-justify transmit data before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data. **Value** — **Description** 0x3 — 4-bit serial data transfer 0x4 — 5-bit serial data transfer 0x5 — 6-bit serial data transfer 0x6 — 7-bit serial data transfer 0x7 — 8-bit serial data transfer 0x8 — 9-bit serial data transfer 0x9 — 10-bit serial data transfer 0xA — 11-bit serial data transfer 0xB — 12-bit serial data transfer 0xC — 13-bit serial data transfer 0xD — 14-bit serial data transfer 0xE — 15-bit serial data transfer 0xF — 16-bit serial data transfer	RW	0x7

ctrlr1

Control register 1 controls the end of serial transfers when in receive-only mode. It is impossible to write to this register when the SPI Master is enabled.The SPI Master is enabled and disabled by writing to the SPIENR register.

ser Fields

Bit	Name	Description	Access	Reset
3:0	ser	Each bit in this register corresponds to a slave select line (spim_ss_x_n] from the SPI Master. When a bit in this register is set (1), the corresponding slave select line from the master is activated when a serial transfer begins. It should be noted that setting or clearing bits in this register have no effect on the corresponding slave select outputs until a transfer is started. Before beginning a transfer, you should enable the bit in this register that corresponds to the slave device with which the master wants to communicate. When not operating in broadcast mode, only one bit in this field should be set. **Value** **Description** 0x0 Slave x Not Selected 0x1 Slave x Selected	RW	0x0

baudr

This register derives the frequency of the serial clock that regulates the data transfer. The 16-bit field in this register defines the spi_m_clk divider value. It is impossible to write to this register when the SPI Master is enabled. The SPI Master is enabled and disabled by writing to the SPIENR register.

Module Instance	Base Address	Register Address

dr

This register is a 16-bit read/write buffer for the transmit/receive FIFOs. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SPI_EN = 1. FIFOs are reset when SPI_EN = 0. The data register occupies 36 32-bit locations in the address map (0x60 to 0xec). These are all aliases for the same data register. This is done to support burst accesses.

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset
15:12	cfs	Selects the length of the control word for the Microwire frame format. The length (in bits) is the value of this field plus 1.	RW	0x0
11	srl	Used for testing purposes only. When internally active, connects the transmit shift register output to the receive shift register input. **Value** **Description** 0x0 Normal Mode Operation 0x1 Test Mode Operation	RW	0x0

<table>
<tr><th>Bit</th><th>Name</th><th>Description</th><th>Access</th><th>Reset</th></tr>
<tr><td>10</td><td>slv_oe</td><td>This bit enables or disables the setting of the spis0_ssi_oe_n output from the SPI Slave. When SLV_OE = 1, the spis0_ssi_oe_n output can never be active. When the spis0_ssi_oe_n output controls the tri-state buffer on the txd output from the slave, a high impedance state is always present on the slave spis0_txd output when SLV_OE = 1. This is useful when the master transmits in broadcast mode (master transmits data to all slave devices). Only one slave may respond with data on the master spis0_rxd line. This bit is enabled after reset and must be disabled by software (when broadcast mode is used), if you do not want this device to respond with data.
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0x0</td><td>Slave txd is enabled</td></tr>
<tr><td>0x1</td><td>Slave txd is disabled</td></tr>
</table></td><td>RW</td><td>0x0</td></tr>
<tr><td>9:8</td><td>tmod</td><td>Selects the mode of transfer for serial communication. This field does not affect the transfer duplicity. Only indicates whether the receive or transmit data are valid. In transmit-only mode, data received from the external device is not valid and is not stored in the receive FIFO memory; it is overwritten on the next transfer. In receive-only mode, transmitted data are not valid. After the first write to the transmit FIFO, the same word is retransmitted for the duration of the transfer. In transmit-and-receive mode, both transmit and receive data are valid. The transfer continues until the transmit FIFO is empty. Data received from the external device are stored into the receive FIFO memory

January 2012	1.0	Initial release.

I^{2}C Controller 20

2014.06.30

cv_54020 Subscribe Send Feedback

The I^{2}C controller provides support for a communication link between integrated circuits on a board. It is a simple two-wire bus which consists of a serial data line (SDA) and a serial clock (SCL) for use in applications such as temperature sensors and voltage level translators to EEPROMs, A/D and D/A converters, CODECs, and many types of microprocessors. †

The hard processor system (HPS) provides four I^{2}C controllers to enable system software to communicate serially with I^{2}C buses. Each I^{2}C controller can operate in master or slave mode, and support standard mode of up to 100 Kbps or fast mode of up to 400 Kbps. These I^{2}C controllers are instances of the Synopsys® DesignWare® APB I^{2}C (DW_apb_i2c) controller.

Each I^{2}C controller must be programmed to operate in either master or slave mode only. Operating as a master and slave simultaneously is not supported. † [43]

Features of the I^{2}C Controller

The I^{2}C controller has the following features:

- Maximum clock speed of up to 400 Kbps
- One of the following I^{2}C operations:
  - A master in an I^{2}C system and programmed only as a master †
  - A slave in an I^{2}C system and programmed only as a slave †
- 7- or 10-bit addressing †
- Mixed read and write combined-format transactions in both 7-bit and 10-bit addressing mode †
- Bulk transmit mode †
- Transmit and receive buffers †
- Handles bit and byte waiting at all bus speeds †
- DMA handshaking interface †

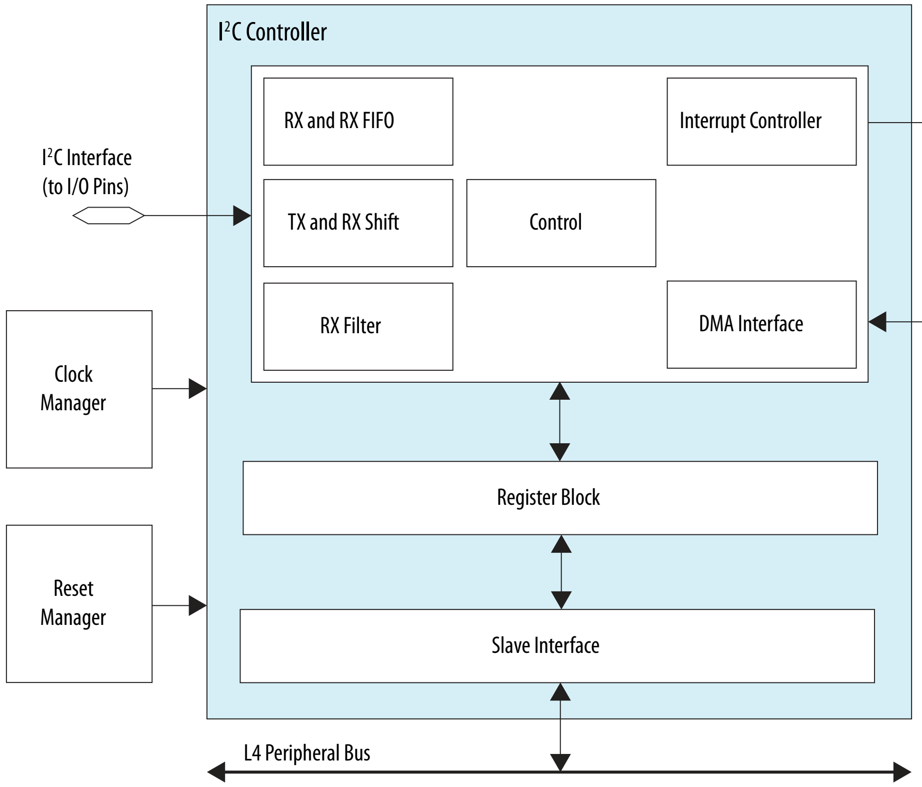
I^{2}C Controller Block Diagram and System Integration

The I^{2}C controller consists of an internal slave interface, an I^{2}C interface, and FIFO logic to buffer data between the two interfaces. †

The host processor accesses data, control, and status information about the I^{2}C controller through a 32-bit slave interface.

Figure 20-1: I^{2}C Controller Block Diagram



The I^{2}C controller consists of the following modules and interfaces:

- Slave interface for control and status register (CSR) accesses and DMA transfers, allowing a master to access the CSRs and the DMA to read or write data directly.
- Two FIFO buffers for transmit and receive data, which hold the Rx FIFO and Tx FIFO buffer register banks and controllers, along with their status levels. †
- Shift logic for parallel-to-serial and serial-to-parallel conversion
    - Rx shift – Receives data into the design and extracts it in byte format. †
    - Tx shift – Presents data supplied by CPU for transfer on the I^{2}C bus. †
- Control logic responsible for implementing the I^{2}C protocol.

- DMA interface that generates handshaking signals to the DMA controller in order to automate the data transfer without CPU intervention. †
- Interrupt controller that generates raw interrupts and interrupt flags, allowing them to be set and cleared. †
- Receive filter for detecting events, such as start and stop conditions, in the bus; for example, start, stop and arbitration lost. †

Functional Description of the I^{2}C Controller

Feature Usage

The I^{2}C controller can operate in standard mode (with data rates of up to 100 Kbps) or fast mode (with data rates less than or equal to 400 Kbps). Additionally, fast mode devices are downward compatible. For instance, fast mode devices can communicate with standard mode devices in 0 to 100 Kbps I^{2}C bus system. However, standard mode devices are not upward compatible and should not be incorporated in a fast-mode I^{2}C bus system as they cannot follow the higher transfer rate and therefore unpredictable states would occur. †

You can attach any I^{2}C controller to an I^{2}C-bus and every device can talk with any master, passing information back and forth. There needs to be at least one master (such as a microcontroller or DSP) on the bus and there can be multiple masters, which require them to arbitrate for ownership. Multiple masters and arbitration are explained later in this chapter. †

Behavior

You can control the I^{2}C controller via software to be in either mode:

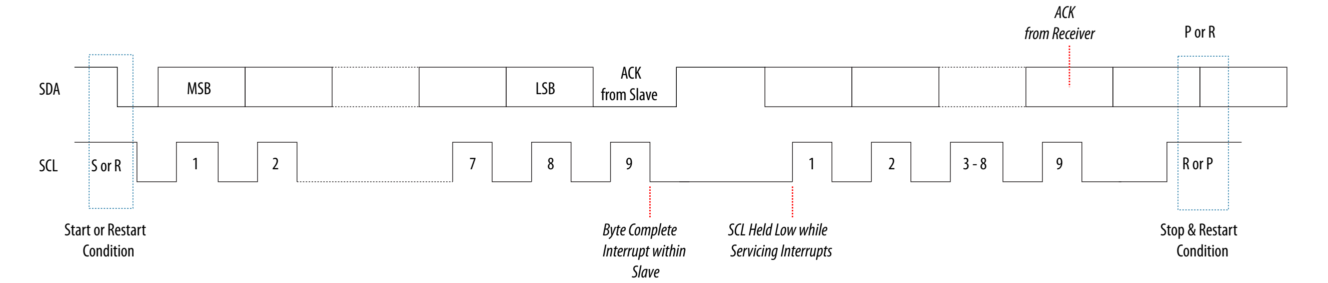
- An I^{2}C master only, communicating with other I^{2}C slaves.
- An I^{2}C slave only, communicating with one or more I^{2}C masters.

The master is responsible for generating the clock and controlling the transfer of data. The slave is responsible for either transmitting or receiving data to/from the master. The acknowledgement of data is sent by the device that is receiving data, which can be either a master or a slave. As mentioned previously, the I^{2}C protocol also allows multiple masters to reside on the I^{2}C bus and uses an arbitration procedure to determine bus ownership. †

Each slave has a unique address that is determined by the system designer. When a master wants to communicate with a slave, the master transmits a START/RESTART condition that is then followed by the slave's address and a control bit (R/W) to determine if the master wants to transmit data or receive data from the slave. The slave then sends an acknowledge (ACK) pulse after the address. †

If the master (master-transmitter) is writing to the slave (slave-receiver), the receiver receives one byte of data. This transaction continues until the master terminates the transmission with a STOP condition. If the master is reading from a slave (master-receiver), the slave transmits (slave-transmitter) a byte of data to the master, and the master then acknowledges the transaction with an ACK pulse. This transaction continues until the master terminates the transmission by not acknowledging (NACK) the transaction after the last byte is received, and then the master issues a STOP condition or addresses another slave after issuing a RESTART condition. †

Figure 20-2: Data transfer on the I^{2}C Bus †



The I^{2}C controller is a synchronous serial interface. The SDA line is a bidirectional signal and changes only while the SCL line is low, except for STOP, START, and RESTART conditions. The output drivers are open-drain or open-collector to perform wire-AND functions on the bus. The maximum number of devices on the bus is limited by only the maximum capacitance specification of 400 pF. Data is transmitted in byte packages. †

START and STOP Generation

When operating as a master, putting data into the transmit FIFO causes the I^{2}C controller to generate a START condition on the I^{2}C bus. In order for the master to complete the transfer and issue a STOP condition it must find a transmit FIFO entry tagged with a stop bit. Allowing the transmit FIFO to empty without a stop bit set, the master will stall the transfer by holding the SCL line low. †

When operating as a slave, the I^{2}C controller does not generate START and STOP conditions, as per the protocol. However, if a read request is made to the I^{2}C controller, it holds the SCL line low until read data has been supplied to it. This stalls the I^{2}C bus until read data is provided to the slave I^{2}C controller, or the I^{2}C controller slave is disabled by writing a 0 to bit 0 of `IC_ENABLE` register. †

Combined Formats

The I^{2}C controller supports mixed read and write combined format transactions in both 7-bit and 10-bit addressing modes. †

The I^{2}C controller does not support mixed address and mixed address format—that is, a 7-bit address transaction followed by a 10-bit address transaction or vice versa—combined format transactions. †

To initiate combined format transfers, the `IC_RESTART_EN` bit in the `IC_CON` register should be set to 1. With this value set and operating as a master, when the I^{2}C controller completes an I^{2}C transfer, it checks the transmit FIFO and executes the next transfer. If the direction of this transfer differs from the previous transfer, the combined format is used to issue the transfer. If the `IC_RESTART_EN` is 0, a STOP will be issued followed by a START condition. Another way to generate the RESTART condition is to set the Restart bit [10] of the `DATA_CMD` register. Regardless if the direction of the transfer changes or not the RESTART condition will be generated.†

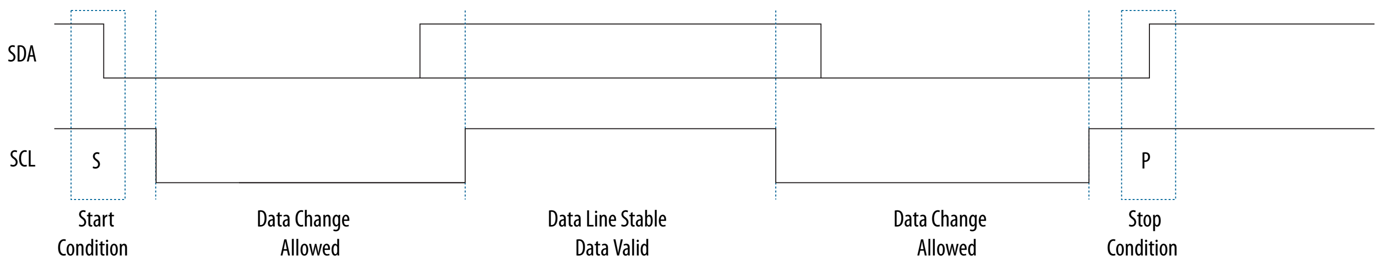
Protocol Details

START and STOP Conditions

When the bus is idle, both the SCL and SDA signals are pulled high through pull-up resistors on the bus. When the master wants to start a transmission on the bus, the master issues a START condition. This is defined to be a high-to-low transition of the SDA signal while SCL is 1. When the master wants to terminate the transmission, the master issues a STOP condition. This is defined to be a low-to-high transition of the SDA line while SCL is 1. †

The following figure shows the timing of the START and STOP conditions. When data is being transmitted on the bus, the SDA line must be stable when SCL is 1. †

Figure 20-3: Timing Diagram for START and STOP Conditions



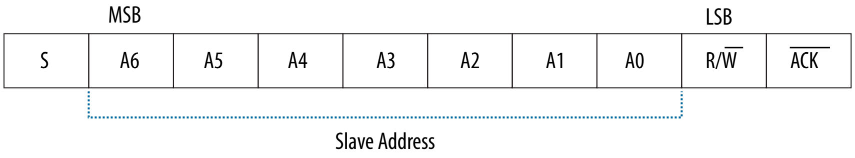
The signal transitions for the START or STOP condition, as shown in the figure, reflect those observed at the output signals of the master driving the I^{2}C bus. Care should be taken when observing the SDA or SCL signals at the input signals of the slave(s), because unequal line delays may result in an incorrect SDA or SCL timing relationship. †

Addressing Slave Protocol

7-Bit Address Format

During the 7-bit address format, the first seven bits (bits 7:1) of the first byte set the slave address and the LSB bit (bit 0) is the R/W bit as shown in the following figure. When bit 0 (R/W) is set to 0, the master writes to the slave. When bit 0 (R/W) is set to 1, the master reads from the slave. †

Figure 20-4: 7- Bit Address Format

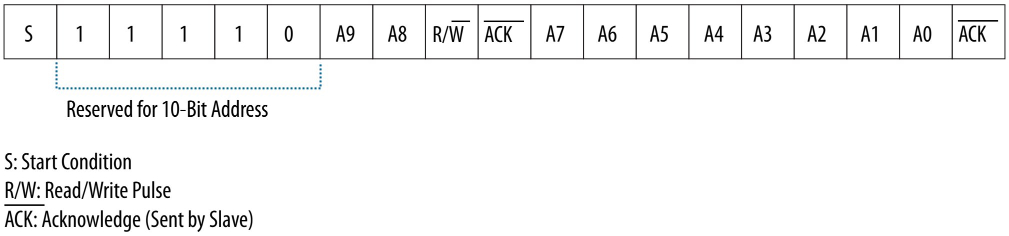


S: Start Condition
$R/\overline{W}$: Read/Write Pulse
$\overline{ACK}$: Acknowledge (Sent by Slave)

10-Bit Address Format

During 10-bit addressing, two bytes are transferred to set the 10-bit address. The transfer of the first byte contains the following bit definition. The first five bits (bits 7:3) notify the slaves that this is a 10-bit transfer followed by the next two bits (bits 2:1), which set the slaves address bits 9:8, and the LSB bit (bit 0) is the R/W bit. The second byte transferred sets bits 7:0 of the slave address. †

Figure 20-5: 10-Bit Address Format



The following table defines the special purpose and reserved first byte addresses. †

Table 20-1: I^2C Definition of Bits in First Byte

Slave Address	R/W Bit	Description
0000 000	0	General call address. The I^2C controller places the data in the receive buffer and issues a general call interrupt.
0000 000	1	START byte. For more details, refer to “START BYTE Transfer Protocol”
0000 001	X	CBUS address. The I^2C controller ignores these accesses.
0000 010	X	Reserved
0000 011	X	Reserved
0000 1XX	X	Unused
1111 1XX	X	Reserved
1111 0XX	X	10-bit slave addressing.

Note to Table: ‘X’ indicates do not care.

Related Information

START BYTE Transfer Protocol on page 20-8

Transmitting and Receiving Protocol

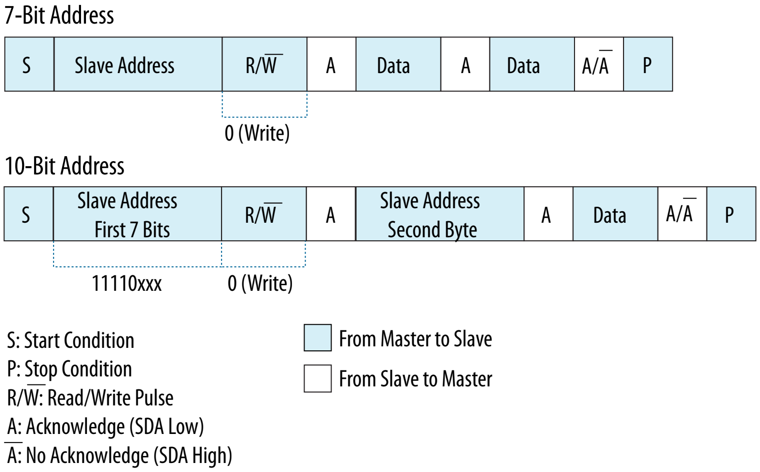
The master can initiate data transmission and reception to or from the bus, acting as either a master-transmitter or master-receiver. A slave responds to requests from the master to either transmit data or receive data to or from the bus, acting as either a slave-transmitter or slave-receiver, respectively. †

Master-Transmitter and Slave-Receiver

All data is transmitted in byte format, with no limit on the number of bytes transferred per data transfer. After the master sends the address and R/W bit or the master transmits a byte of data to the slave, the slave-receiver must respond with the acknowledge signal (ACK). When a slave-receiver does not respond with an ACK pulse, the master aborts the transfer by issuing a STOP condition. The slave must leave the SDA line high so that the master can abort the transfer. †

If the master-transmitter is transmitting data as shown in the following figure, then the slave-receiver responds to the master-transmitter with an ACK pulse after every byte of data is received. †

Figure 20-6: Master-Transmitter Protocol †



Master-Receiver and Slave-Transmitter

If the master is receiving data as shown in the following figure, then the master responds to the slave-transmitter with an ACK pulse after a byte of data has been received, except for the last byte. This is the way the master-receiver notifies the slave-transmitter that this is the last byte. The slave-transmitter relinquishes the SDA line after detecting the No Acknowledge (NACK) bit so that the master can issue a STOP condition. †

When a master does not want to relinquish the bus with a STOP condition, the master can issue a RESTART condition. This is identical to a START condition except it occurs after the ACK pulse. Operating in master mode, the I^{2}C controller can then communicate with the same slave using a transfer of a different direction. For a description of the combined format transactions that the I^{2}C controller supports, refer to “Combined Formats” section of this chapter. †

Note: The I^{2}C controller must be inactive on the serial port (`I2C_DYNAMIC_TAR_UPDATE` = 1) before the target slave address register, `IC_TAR` can be reprogrammed. †

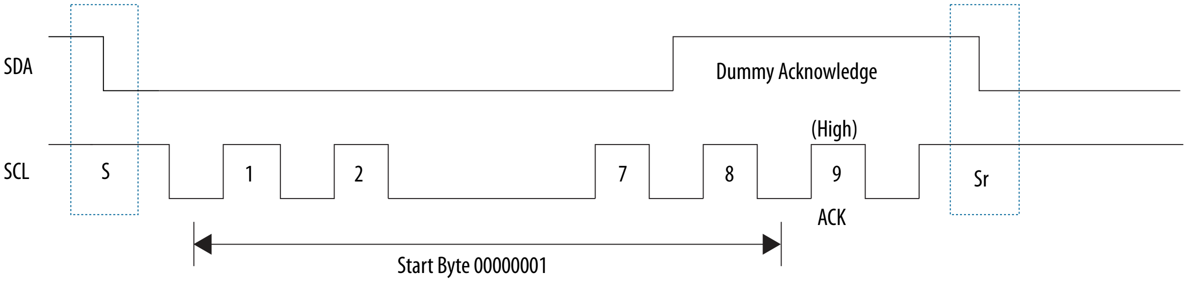
Combined Formats on page 20-4

START BYTE Transfer Protocol

The START BYTE transfer protocol is set up for systems that do not have an on-board dedicated I^{2}C hardware module. When the I^{2}C controller is set as a slave, it always samples the I^{2}C bus at the highest speed supported so that it never requires a START BYTE transfer. However, when I^{2}C controller is set as a master, it supports the generation of START BYTE transfers at the beginning of every transfer in case a slave device requires it. This protocol consists of seven zeros being transmitted followed by a 1, as illustrated in the following figure. This allows the processor that is polling the bus to under-sample the address phase until the microcontroller detects a 0. Once the microcontroller detects a 0, it switches from the under sampling rate to the correct rate of the master. †

Figure 20-8: START BYTE Transfer †



The START BYTE has the following procedure: †

1. Master generates a START condition. †
2. Master transmits the START byte (0000 0001). †
3. Master transmits the ACK clock pulse. (Present only to conform with the byte handling format used on the bus) †
4. No slave sets the ACK signal to 0. †
5. Master generates a RESTART (R) condition. †

A hardware receiver does not respond to the START BYTE because it is a reserved address and resets after the RESTART condition is generated. †

Multiple Master Arbitration

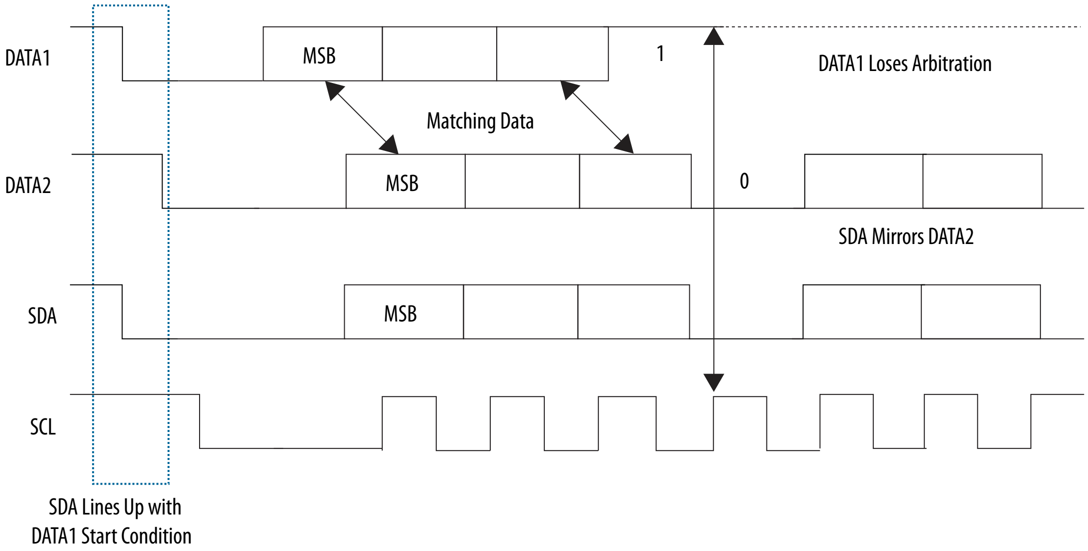
The I^{2}C controller bus protocol allows multiple masters to reside on the same bus. If there are two masters on the same I^{2}C-bus, there is an arbitration procedure if both try to take control of the bus at the same time by simultaneously generating a START condition. Once a master (for example, a microcontroller) has control of the bus, no other master can take control until the first master sends a STOP condition and places the bus in an idle state. †

Arbitration takes place on the SDA line, while the SCL line is 1. The master, which transmits a 1 while the other master transmits 0, loses arbitration and turns off its data output stage. The master that lost arbitration can continue to generate clocks until the end of the byte transfer. If both masters are addressing the same slave device, the arbitration could go into the data phase. †

Upon detecting that it has lost arbitration to another master, the I^{2}C controller stops generating SCL. †

The following figure illustrates the timing of two masters arbitrating on the bus.

Figure 20-9: Multiple Master Arbitration †



The bus control is determined by address or master code and data sent by competing masters, so there is no central master nor any order of priority on the bus. †

Arbitration is not allowed between the following conditions: †

- A RESTART condition and a data bit †
- A STOP condition and a data bit †
- A RESTART condition and a STOP condition †

Slaves are not involved in the arbitration process. †

Clock Synchronization

When two or more masters try to transfer information on the bus at the same time, they must arbitrate and synchronize the SCL clock. All masters generate their own clock to transfer messages. Data is valid only during the high period of SCL clock. Clock synchronization is performed using the wired-AND connection to the SCL signal. When the master transitions the SCL clock to 0, the master starts counting the low time of the SCL clock and transitions the SCL clock signal to 1 at the beginning of the next clock period. However, if another master is holding the SCL line to 0, then the master goes into a HIGH wait state until the SCL clock line transitions to 1. †

All masters then count off their high time, and the master with the shortest high time transitions the SCL line to 0. The masters then counts out their low time and the one with the longest low time forces the other master into a HIGH wait state. Therefore, a synchronized SCL clock is generated, which is illustrated in the following figure. Optionally, slaves may hold the SCL line low to slow down the timing on the I^{2}C bus. †

Figure 20-10: Multiple Master Clock Synchronization †

SCL Low Transition Resets All Clocks; Start Counting Their Low Periods
SCL Transitions High When All Clocks Are in a High State

Clock Frequency Configuration

When you configure the I^{2}C controller as a master, the SCL count registers must be set before any I^{2}C bus transaction can take place in order to ensure proper I/O timing. † There are four SCL count registers:

- Standard speed I^{2}C clock SCL high count, `IC_SS_SCL_HCNT` †
- Standard speed I^{2}C clock SCL low count, `IC_SS_SCL_LCNT` †
- Fast speed I^{2}C clock SCL high count, `IC_FS_SCL_HCNT` †
- Fast speed I^{2}C clock SCL low count, `IC_FS_SCL_LCNT` †

It is not necessary to program any of the SCL count registers if the I^{2}C controller is enabled to operate only as an I^{2}C slave, since these registers are used only to determine the SCL timing requirements for operation as an I^{2}C master. †

Minimum High and Low Counts

When the I^2C controller operates as an I^2C master in both transmit and receive transfers, the minimum value that can be programmed in the SCL low count registers is 8 while the minimum value allowed for the SCL high count registers is 6. †

The minimum value of 8 for the low count registers is due to the time required for the I^2C controller to drive SDA after a negative edge of SCL. The minimum value of 6 for the high count register is due to the time required for the I^2C controller to sample SDA during the high period of SCL. †

The I^2C controller adds one cycle to the low count register values in order to generate the low period of the SCL clock.

The I^2C controller adds seven cycles to the high count register values in order to generate the high period of the SCL clock. This is due to the following factors: †

- The digital filtering applied to the SCL line incurs a delay of four `l4_sp_clk` cycles. This filtering includes metastability removal and a 2-out-of-3 majority vote processing on SDA and SCL edges. †
- Whenever SCL is driven 1 to 0 by the I^2C controller—that is, completing the SCL high time—an internal logic latency of three `l4_sp_clk` cycles incurs. †

Consequently, the minimum SCL low time of which the I^2C controller is capable is nine (9) `l4_sp_clk` periods (8+1), while the minimum SCL high time is thirteen (13) `l4_sp_clk` periods (6+1+3+3). †

Calculating High and Low Counts

The calculations below show an example of how to calculate SCL high and low counts for each speed mode in the I^2C controller.

The equation to calculate the proper number of `l4_sp_clk` clock pulses required for setting the proper SCL clocks high and low times is as follows: †

Table 20-2: Equation

IC_HCNT = ceil(MIN_SCL_HIGHtime*OSCFREQ)
IC_LCNT = ceil(MIN_SCL_LOWtime*OSCFREQ)
MIN_SCL_HIGHtime = minimum high period
MIN_SCL_HIGHtime =
4000 ns for 100 kbps
600 ns for 400 kbps
60 ns for 3.4 Mbs, bus loading = 100pF
160 ns for 3.4 Mbs, bus loading = 400pF
MIN_SCL_LOWtime = minimum low period
MIN_SCL_LOWtime =
4700 ns for 100 kbps
1300 ns for 400 kbps
120 ns for 3.4Mbs, bus loading = 100pF
320 ns for 3.4Mbs, bus loading = 400pF
OSCFREQ = l4_sp_clk clock frequency (Hz)
For example:
OSCFREQ = 100 MHz
I2Cmode = fast, 400 kbps
MIN_SCL_HIGHtime = 600 ns
MIN_SCL_LOWtime = 1300 ns
IC_HCNT = ceil(600 ns * 100 MHz) IC_HCNTSCL PERIOD = 60
IC_LCNT = ceil(1300 ns * 100 MHz) IC_LCNTSCL PERIOD = 130
Actual MIN_SCL_HIGHtime = 60*(1/100 MHz) = 600 ns
Actual MIN_SCL_LOWtime = 130*(1/100 MHz) = 1300 ns †

SDA Hold Time

The I^{2}C protocol specification requires 300 ns of hold time on the SDA signal in standard and fast speed modes. Board delays on the SCL and SDA signals can mean that the hold time requirement is met at the I^{2}C master, but not at the I^{2}C slave (or vice-versa). As each application encounters differing board delays, the I^{2}C controller contains a software programmable register, IC_SDA_HOLD, to enable dynamic adjustment of the SDA hold time. †

DMA Controller Interface

The I^{2}C controller supports DMA signaling to indicate when data is ready to be read or when the transmit FIFO needs data. This support requires 2 DMA channels, one for transmit data and one for receive data. The I^{2}C controller supports both single and burst DMA transfers. System software can choose the DMA burst mode by programming an appropriate value into the threshold registers. The recommended setting of the FIFO threshold register value is half full.

To enable the DMA controller interface on the I^{2}C controller, you must write to the DMA control register (DMACR) bits. Writing a 1 into the TDMAE bit field of DMACR register enables the I^{2}C controller transmit handshaking interface. Writing a 1 into the RDMAE bit field of the DMACR register enables the I^{2}C controller receive handshaking interface. †

Related Information

DMA Controller on page 16-1
For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

Clocks

Each I^{2}C controller is connected to the `l4_sp_clk` clock, which clocks transfers in standard and fast mode. The clock input is driven by the clock manager.

Related Information

Clock Manager on page 2-1
For more information, refer to *Clock Manager* chapter.

Resets

Each I^{2}C controller has a separate reset signal. The reset manager drives the signals on a cold or warm reset.

Related Information

Reset Manager on page 3-1
For more information, refer to *Reset Manager* chapter.

Interface Pins

All instances of the I^{2}C controller connect to external pins through pin multiplexers. Pin multiplexing allows all instances to function simultaneously and independently. The pins must be connected to a pull-up resistors and the I^{2}C bus capacitance cannot exceed 400 pF.

Table 20-3: I^{2}C Controller Interface Pins

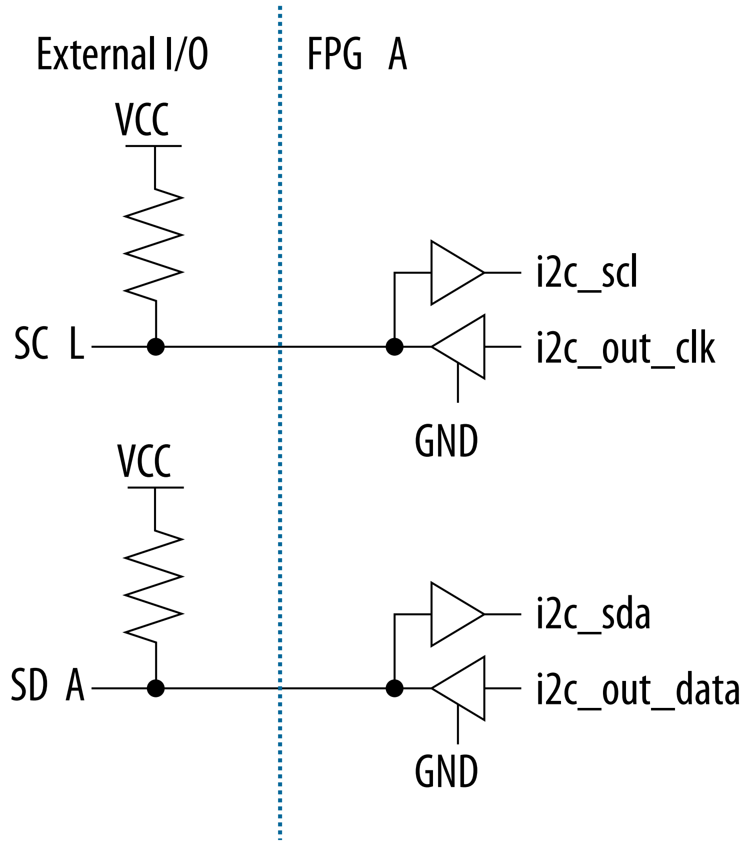
Pin Name	Signal Width	Direction	Description
SCL	1 bit	Bidirectional	Serial clock
SDA	1 bit	Bidirectional	Serial data

Table 20-4: HPS I^{2}C Signals for FPGA Routing

Signal Name	Signal Width	Direction	Description
i2c<#>_scl	1 bit	Input	Incoming I^{2}C clock source. This is the input SCL signal

Signal Name	Signal Width	Direction	Description
i2c<#>_out_clk	1 bit	Output	Outgoing I^2C clock enable. Output SCL signal. This signal is logically inverted and is synchronous to the HPS peripheral clock
i2c<#>_sda	1 bit	Input	Incoming I^2C data. This is the input SDA signal.
i2c<#>_out_data	1 bit	Output	Outgoing I^2C data enable. Output SDA signal. This signal is logically inverted and is synchronous to the HPS peripheral clock.

Figure 20-11: I^2C interface in FPGA fabric



The figure above shows the typical connection on the I^2C interface in FPGA fabric with `alt_iobuff`.

For both I2C clock and data, external IO pins are open drain connection. When output enables `i2c_out_data` and `i2c_out_clk` are asserted, external signal will be driven to ground.

I²C Controller Programming Model

This section describes the programming model for the I²C controllers based on the two master and slave operation modes. †

Note: Each I²C controller should be set to operate only as an I²C master or as an I²C slave, never set both simultaneously. Ensure that bit 6 (`IC_SLAVE_DISABLE`) and 0 (`IC_MASTER_MODE`) of the `IC_CON` register are never set to 0 and 1, respectively. †

Slave Mode Operation

Initial Configuration

To use the I²C controller as a slave, perform the following steps: †

1. Disable the I²C controller by writing a 0 to bit 0 of the `IC_ENABLE` register. †
2. Write to the `IC_SAR` register (bits 9:0) to set the slave address. This is the address to which the I²C controller responds. †

   Note: The reset value for the I²C controller slave address is 0x55. If you are using 0x55 as the slave address, you can safely skip this step.
3. Write to the `IC_CON` register to specify which type of addressing is supported (7- or 10-bit by setting bit 3). Enable the I²C controller in slave-only mode by writing a 0 into bit 6 (`IC_SLAVE_DISABLE`) and a 0 to bit 0 (`MASTER_MODE`). †

   Note: Slaves and masters do not have to be programmed with the same type of addressing 7- or 10-bit address. For instance, a slave can be programmed with 7-bit addressing and a master with 10-bit addressing, and vice versa. †
4. Enable the I²C controller by writing a 1 in bit 0 of the `IC_ENABLE` register. †

Slave-Transmitter Operation for a Single Byte

When another I²C master device on the bus addresses the I²C controller and requests data, the I²C controller acts as a slave-transmitter and the following steps occur: †

1. The other I²C master device initiates an I²C transfer with an address that matches the slave address in the `IC_SAR` register of the I²C controller †
2. The I²C controller acknowledges the sent address and recognizes the direction of the transfer to indicate that it is acting as a slave-transmitter. †
3. The I²C controller asserts the `RD_REQ` interrupt (bit 5 of the `IC_RAW_INTR_STAT` register) and waits for software to respond. †

If the RD_REQ interrupt has been masked, due to bit 5 of the IC_INTR_MASK register (M_RD_REQ bit field) being set to 0, then it is recommended that you instruct the CPU to perform periodic reads of the IC_RAW_INTR_STAT register. †

- Reads that indicate bit 5 of the IC_RAW_INTR_STAT register (R_RD_REQ bit field) being set to 1 must be treated as the equivalent of the RD_REQ interrupt being asserted. †
- Software must then act to satisfy the I²C transfer. †
- The timing interval used should be in the order of 10 times the fastest SCL clock period the I²C controller can handle. For example, for 400 Kbps, the timing interval is 25 us. †

  Note: The value of 10 is recommended here because this is approximately the amount of time required for a single byte of data transferred on the I²C bus.†

4. If there is any data remaining in the TX FIFO before receiving the read request, the I²C controller asserts a TX_ABRT interrupt (bit 6 of the IC_RAW_INTR_STAT register) to flush the old data from the TX FIFO. †

   Note: Because the I²C controller's TX FIFO is forced into a flushed/reset state whenever a TX_ABRT event occurs, it is necessary for software to release the I²C controller from this state by reading the IC_CLR_TX_ABRT register before attempting to write into the TX FIFO. For more information, refer to the C_RAW_INTR_STAT register description in the register map.†

   If the TX_ABRT interrupt has been masked, due to of IC_INTR_MASK[6] register (M_TX_ABRT bit field) being set to 0, then it is recommended that the CPU performs periodic reads of the IC_RAW_INTR_STAT register. †

   - Reads that indicate bit 6 (R_TX_ABRT) being set to 1 must be treated as the equivalent of the TX_ABRT interrupt being asserted. †
   - There is no further action required from software. †
   - The timing interval used should be similar to that described in the previous step for the IC_RAW_INTR_STAT[5] register. †
5. Software writes to the DAT bits of the IC_DATA_CMD register with the data to be written and writes a 0 in bit 8.†
6. Software must clear the RD_REQ and TX_ABRT interrupts (bits 5 and 6, respectively) of the IC_RAW_INTR_STAT register before proceeding. †

   If the RD_REQ and/or TX_ABRT interrupts have been masked, then clearing of the IC_RAW_INTR_STAT register will have already been performed when either the R_RD_REQ or R_TX_ABRT bit has been read as 1. †
7. The I²C controller transmits the byte. †
8. The master may hold the I²C bus by issuing a RESTART condition or release the bus by issuing a STOP condition. †

Slave-Receiver Operation for a Single Byte

When another I²C master device on the bus addresses the I²C controller and is sending data, the I²C controller acts as a slave-receiver and the following steps occur:†

1. The other I²C master device initiates an I²C transfer with an address that matches the I²C controller's slave address in the IC_SAR register. †
2. The I²C controller acknowledges the sent address and recognizes the direction of the transfer to indicate that the I²C controller is acting as a slave-receiver. †
3. I²C controller receives the transmitted byte and places it in the receive buffer. †

   Note: If the RX FIFO is completely filled with data when a byte is pushed, then an overflow occurs and the I²C controller continues with subsequent I²C transfers. Because a NACK is not generated, software must recognize the overflow when indicated by the I²C controller (by the

R_RX_OVER bit in the IC_INTR_STAT register) and take appropriate actions to recover from lost data. Hence, there is a real time constraint on software to service the RX FIFO before the latter overflow as there is no way to reapply pressure to the remote transmitting master. †

4. I^{2}C controller asserts the RX_FULL interrupt (IC_RAW_INTR_STAT[2] register). †

   If the RX_FULL interrupt has been masked, due to setting IC_INTR_MASK[2] register to 0 or setting IC_TX_TL to a value larger than 0, then it is recommended that the CPU does periodic reads of the IC_STATUS register. Reads of the IC_STATUS register, with bit 3 (RFNE) set at 1, must then be treated by software as the equivalent of the RX_FULL interrupt being asserted. †
5. Software may read the byte from the IC_DATA_CMD register (bits 7:0). †
6. The other master device may hold the I^{2}C bus by issuing a RESTART condition or release the bus by issuing a STOP condition. †

Slave-Transfer Operation for Bulk Transfers

In the standard I^{2}C protocol, all transactions are single byte transactions and the programmer responds to a remote master read request by writing one byte into the slave's TX FIFO. When a slave (slave-transmitter) is issued with a read request (RD_REQ) from the remote master (master-receiver), at a minimum there should be at least one entry placed into the slave-transmitter's TX FIFO. The I^{2}C controller is designed to handle more data in the TX FIFO so that subsequent read requests can receive that data without raising an interrupt to request more data. Ultimately, this eliminates the possibility of significant latencies being incurred between raising the interrupt for data each time had there been a restriction of having only one entry placed in the TX FIFO. †

This mode only occurs when I^{2}C controller is acting as a slave-transmitter. If the remote master acknowledges the data sent by the slave-transmitter and there is no data in the slave's TX FIFO, the I^{2}C controller raises the read request interrupt (RD_REQ) and waits for data to be written into the TX FIFO before it can be sent to the remote master. †

If the RD_REQ interrupt is masked, due to bit 5 (M_RD_REQ) of the IC_INTR_STAT register being set to 0, then it is recommended that the CPU does periodic reads of the IC_RAW_INTR_STAT register. Reads of IC_RAW_INTR_STAT that return bit 5 (R_RD_REQ) set to 1 must be treated as the equivalent of the RD_REQ interrupt referred to in this section.†

The RD_REQ interrupt is raised upon a read request, and like interrupts, must be cleared when exiting the interrupt service handling routine (ISR). The ISR allows you to either write 1 byte or more than 1 byte into the TX FIFO. During the transmission of these bytes to the master, if the master acknowledges the last byte then the slave must raise the RD_REQ again because the master is requesting for more data. †

If the programmer knows in advance that the remote master is requesting a packet of n bytes, then when another master addresses the I^{2}C controller and requests data, the TX FIFO could be written with n number bytes and the remote master receives it as a continuous stream of data. For example, the I^{2}C controller slave continues to send data to the remote master as long as the remote master is acknowledging the data sent and there is data available in the TX FIFO. There is no need to issue RD_REQ again. †

If the remote master is to receive n bytes from the I^{2}C controller but the programmer wrote a number of bytes larger than n to the TX FIFO, then when the slave finishes sending the requested n bytes, it clears the TX FIFO and ignores any excess bytes. †

The I^{2}C controller generates a transmit abort (TX_ABRT) event to indicate the clearing of the TX FIFO in this example. At the time an ACK/NACK is expected, if a NACK is received, then the remote master has all the data it wants. At this time, a flag is raised within the slave's state machine to clear the leftover data in the TX FIFO. This flag is transferred to the processor bus clock domain where the FIFO exists and the contents of the TX FIFO are cleared at that time. †

Master Mode Operation

Initial Configuration

For master mode operation, the target address and address format can be changed dynamically without having to disable the I^{2}C controller. This feature is only applicable when the I^{2}C controller is acting as a master because the slave requires the component to be disabled before any changes can be made to the address. To use the I^{2}C controller as a master, perform the following steps: †

For multiple I^{2}C transfers, perform additional writes to the Tx FIFO such that the Tx FIFO does not become empty during the I^{2}C transaction. IF the Tx FIFO is completely emptied at any stage, then the master stalls the transfer by holding the SCL line low because there was no stop bit indicating the master to issue a STOP. The master will complete the transfer when it finds a Tx FIFO entry tagged with a Stop bit.

1. Disable the I^{2}C controller by writing 0 to bit 0 of the `IC_ENABLE` register. †
2. Write to the `IC_CON` register to set the maximum speed mode supported for slave operation (bits 2:1) and to specify whether the I^{2}C controller starts its transfers in 7/10 bit addressing mode when the device is a slave (bit 3). †
3. Write to the `IC_TAR` register the address of the I^{2}C device to be addressed. It also indicates whether a General Call or a START BYTE command is going to be performed by I^{2}C. The desired speed of the I^{2}C controller master-initiated transfers, either 7-bit or 10-bit addressing, is controlled by the `IC_10BITADDR_MASTER` bit field (bit 12). †
4. Enable the I^{2}C controller by writing a 1 in bit 0 of the `IC_ENABLE` register. †
5. Now write the transfer direction and data to be sent to the `IC_DATA_CMD` register. If the `IC_DATA_CMD` register is written before the I^{2}C controller is enabled, the data and commands are lost as the buffers are kept cleared when the I^{2}C controller is not enabled. †

Dynamic IC_TAR or IC_10BITADDR_MASTER Update

The I^{2}C controller supports dynamic updating of the `IC_TAR` (bits 9:0) and `IC_10BITADDR_MASTER` (bit 12) bit fields of the `IC_TAR` register. You can dynamically write to the `IC_TAR` register provided the following conditions are met: †

- The I^{2}C controller is not enabled (`IC_ENABLE`=0); †
- The I^{2}C controller is enabled (`IC_ENABLE`=1); AND I^{2}C controller is NOT engaged in any Master (TX, RX) operation (`IC_STATUS[5]`=0); AND I^{2}C controller is enabled to operate in Master mode (`IC_CON[0]`=1); AND there are no entries in the TX FIFO (`IC_STATUS[2]`=1) †

Master Transmit and Master Receive

The I^{2}C controller supports switching back and forth between reading and writing dynamically. To transmit data, write the data to be written to the lower byte of the I^{2}C Rx/Tx Data Buffer and Command Register (`IC_DATA_CMD`). The CMD bit [8] should be written to 0 for I^{2}C write operations. Subsequently, a read command may be issued by writing "don't cares" to the lower byte of the `IC_DATA_CMD` register, and a 1 should be written to the CMD bit.†

Disabling the I^{2}C Controller

The register IC_ENABLE_STATUS is added to allow software to unambiguously determine when the hardware has completely shutdown in response to the IC_ENABLE register being set from 1 to 0. †

1. Define a timer interval (ti2c_poll) equal to the 10 times the signaling period for the highest I^{2}C transfer speed used in the system and supported by the I^{2}C controller. For example, if the highest I^{2}C transfer mode is 400 Kbps, then ti2c_poll is 25 us. †
2. Define a maximum time-out parameter, MAX_T_POLL_COUNT, such that if any repeated polling operation exceeds this maximum value, an error is reported. †
3. Execute a blocking thread/process/function that prevents any further I^{2}C master transactions to be started by software, but allows any pending transfers to be completed.
   - This step can be ignored if the I^{2}C controller is programmed to operate as an I^{2}C slave only. †
4. The variable POLL_COUNT is initialized to zero. †
5. Set IC_ENABLE to 0. †
6. Read the IC_ENABLE_STATUS register and test the IC_EN bit (bit 0). Increment POLL_COUNT by one. If POLL_COUNT >= MAX_T_POLL_COUNT, exit with the relevant error code. †
7. If IC_ENABLE_STATUS[0] is 1, then sleep for ti2c_poll and proceed to the previous step. Otherwise, exit with a relevant success code. †

DMA Controller Operation

To enable the DMA controller interface on the I^{2}C controller, you must write the DMA Control Register (IC_DMA_CR). Writing a 1 to the TDMAE bit field of IC_DMA_CR register enables the I^{2}C controller transmit handshaking interface. Writing a 1 to the RDMAE bit field of the IC_DMA_CR register enables the I^{2}C controller receive handshaking interface.†

The FIFO buffer depth (FIFO_DEPTH) for both the RX and TX buffers in the I^{2}C controller is 64 entries.

Related Information

DMA Controller on page 16-1
For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

Transmit FIFO Underflow

During I^{2}C serial transfers, transmit FIFO requests are made to the DMA controller whenever the number of entries in the transmit FIFO is less than or equal to the value in DMA Transmit Data Level Register (IC_DMA_TDLR), also known as the watermark level. The DMA controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length. †

Note: Data should be fetched from the DMA often enough for the transmit FIFO to perform serial transfers continuously, that is, when the FIFO begins to empty, another DMA request should be triggered. Otherwise, the FIFO will run out of the data (underflow) causing the maser to stall the transfer by holding the SCL line low. To prevent this condition, you must set the watermark level correctly.†

Related Information

DMA Controller on page 16-1
For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

Transmit Watermark Level

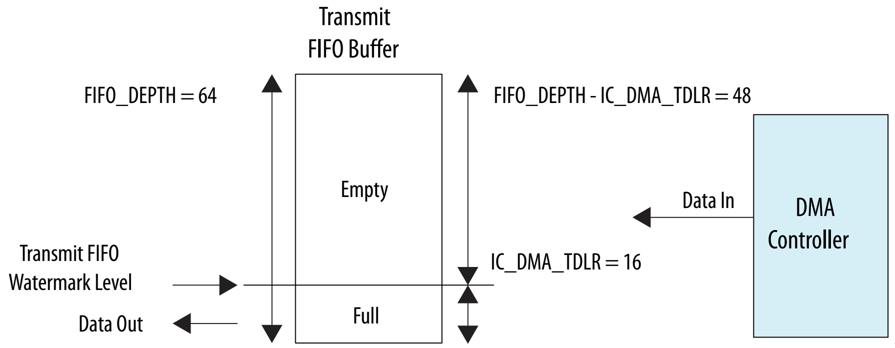
Consider the example where the assumption is made: †

DMA burst length = `FIFO_DEPTH` - `IC_DMA_TDLR` †

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO. Consider the following two different watermark level settings: †

- Case 1: `IC_DMA_TDLR` = 16: †
  - Transmit FIFO watermark level = `IC_DMA_TDLR` = 16: †
  - DMA burst length = `FIFO_DEPTH` - `IC_DMA_TDLR` = 48: †
  - I^2C transmit `FIFO_DEPTH` = 64: †
  - Block transaction size = 240: †

Figure 20-12: Transmit FIFO Watermark Level = 16



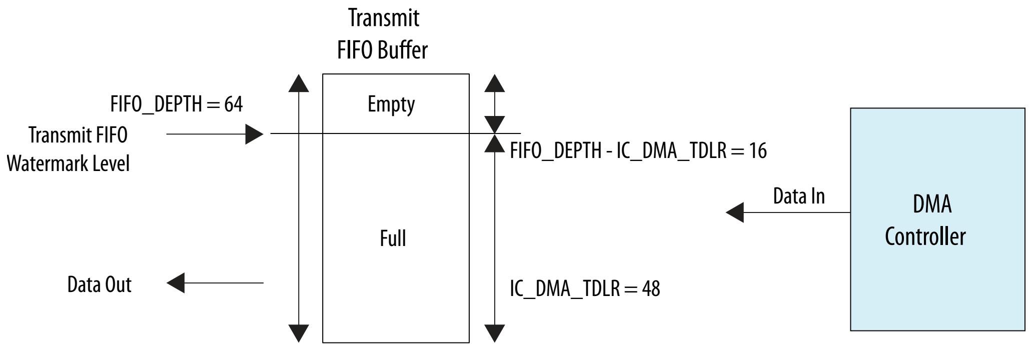
The number of burst transactions needed equals the block size divided by the number of data items per burst:

Block transaction size/DMA burst length = 240/48 = 5

The number of burst transactions in the DMA block transfer is 5. But the watermark level, `IC_DMA_TDLR`, is quite low. Therefore, the probability of transmit underflow is high where the I^2C serial transmit line needs to transmit data, but there is no data left in the transmit FIFO. This occurs because the DMA has not had time to service the DMA request before the FIFO becomes empty.

- Case 2: `IC_DMA_TDLR` = 48 †
  - Transmit FIFO watermark level = `IC_DMA_TDLR` = 48 †
  - DMA burst length = `FIFO_DEPTH` - `IC_DMA_TDLR` = 16 †
  - I^2C transmit `FIFO_DEPTH` = 64 †
  - Block transaction size = 240 †

Figure 20-13: Transmit FIFO Watermark Level = 48



Number of burst transactions in block: †

Block transaction size/DMA burst length = 240/16 = 15 †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, `IC_ DMA_TDLR`, is high. Therefore, the probability of I^2C transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the I^2C transmit FIFO becomes empty. †

Thus, the second case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case. †

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the I^2C transmits data to the rate at which the DMA can respond to destination burst requests. †

Transmit FIFO Overflow

Setting the DMA burst length to a value greater than the watermark level that triggers the DMA request might cause overflow when there is not enough space in the transmit FIFO to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

DMA burst length <= `FIFO_DEPTH` - `IC_DMA_TDLR`

In case 2: `IC_DMA_TDLR` = 48, the amount of space in the transmit FIFO at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO may be full, but not overflowed, at the completion of the burst transaction. †

Therefore, for optimal operation, DMA burst length should be set at the FIFO level that triggers a transmit DMA request; that is: †

DMA burst length = `FIFO_DEPTH` - `IC_DMA_TDLR`

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO will not be full at the end of a DMA burst transfer if the I^2C controller has successfully transmitted one data item or more on the I^2C serial transmit line during the transfer. †

Receive FIFO Overflow

During I^{2}C serial transfers, receive FIFO requests are made to the DMA whenever the number of entries in the receive FIFO is at or above the DMA Receive Data Level Register, that is IC_DMA_RDLR + 1. This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO. †

Data should be fetched by the DMA often enough for the receive FIFO to accept serial transfers continuously, that is, when the FIFO begins to fill, another DMA transfer is requested. Otherwise the FIFO will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

Receive Watermark Level

Similar to choosing the transmit watermark level described earlier, the receive watermark level, IC_DMA_RDLR + 1, should be set to minimize the probability of overflow, as shown in the Receive FIFO Buffer diagram. It is a trade off between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Receive FIFO Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

DMA burst length = IC_DMA_RDLR + 1

If the number of data items in the receive FIFO is equal to the source burst length at the time of the burst request is made, the receive FIFO may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, IC_DMA_RDLR + 1. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can avoid underflow and improve bus utilization. †

Note: The receive FIFO will not be empty at the end of the source burst transaction if the I^{2}C controller has successfully received one data item or more on the I^{2}C serial receive line during the burst. †

ic_con Fields

Bit	Name	Description	Access	Reset
6	ic_slave_disable	This bit controls whether I2C has its slave disabled. The slave will be disabled, after reset. NOTE: Software should ensure that if this bit is written with 0, then bit [0] of this register should also be written with a 0. **Value** — **Description** 0x1 — slave disable 0x0 — slave enable	RW	0x1
5	ic_restart_en	Determines whether RESTART conditions may be sent when acting as a master. Some older slaves do not support handling RESTART conditions; however, RESTART conditions are used in several I2C operations. When RESTART is disabled, the master is prohibited from performing the following functions - Changing direction within a transfer (split), - Sending a START BYTE, - High-speed mode operation, - Combined format transfers in 7-bit addressing modes, - Read operation with a 10-bit address, - Sending multiple bytes per transfer, By replacing RESTART condition followed by a STOP and a subsequent START condition, split operations are broken down into multiple I2C transfers. If the above operations are performed, it will result in setting bit [6](tx_abort) of the Raw Interrupt Status Register. **Value** — **Description** 0x0 — restart master disable 0x1 — restart master enable	RW	0x1

Bit	Name	Description	Access	Reset
4	`ic_10bitaddr_master`	This bit controls whether the I2C starts its transfers in 7-or 10-bit addressing mode when acting as a master. **Value** — **Description** 0x0 — 7-bit addressing 0x1 — 10-bit addressing	RW	0x1
3	`ic_10bitaddr_slave`	When acting as a slave, this bit controls whether the I2C responds to 7- or 10-bit addresses. In 7-bit addressing, only the lower 7 bits of the Slave Address Register are compared. The I2C responds will only respond to 10-bit addressing transfers that match the full 10 bits of the Slave Address register. **Value** — **Description** 0x0 — 7-bit addressing 0x1 — 10-bit addressing	RW	0x1
2:1	`speed`	These bits control at which speed the I2C operates, its setting is relevant only if one is operating the I2C in master mode. Hardware protects against illegal values being programmed by software. This field should be programmed only with standard or fast speed. **Value** — **Description** 0x1 — standard mode (100 kbit/s) 0x2 — fast mode (400 kbit/s)	RW	0x2
0	`master_mode`	This bit controls whether the i2c master is enabled. NOTE: Software should ensure that if this bit is written with '1', then bit 6 should also be written with a '1'. **Value** — **Description** 0x0 — master disabled 0x1 — master enabled	RW	0x1

ic_tar

This register can be written to only when the ic_enable register is set to 0. This register is 13 bits wide. All bits can be dynamically updated as long as any set of the following conditions are true, (Enable Register bit 0 is set to 0) or (Enable Register bit 0 is set to 1 AND (I2C is NOT engaged in any Master [tx, rx] operation [ic_status register mst_activity bit 5 is set to 0]) AND (I2C is enabled to operate in Master mode[ic_con bit[0] is set to one]) AND (there are NO entries in the TX FIFO Register [IC_STATUS bit [2] is set to 1])

RW 0x0</td></tr>
</table>

ic_data_cmd Fields

Bit	Name	Description	Access	Reset
10	`restart`	This bit controls whether a RESTART is issued before the byte is sent or received. 1 = A RESTART is issued before the data is sent/received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command. 0 = A RESTART is issued only if the transfer direction is changing from the previous command. **Value** / **Description** 0x1 Issue Restart 0x0 Issue Restart On Direction Change	`WO`	`0x0`
9	`stop`	This bit controls whether a STOP is issued after the byte is sent or received. 1 = STOP is issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master immediately tries to start a new transfer by issuing a START and arbitrating for the bus. 0 = STOP is not issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master continues the current transfer by sending/ receiving data bytes according to the value of the CMD bit. If the Tx FIFO is empty, the master holds the SCL line low and stalls the bus until a new command is available in the Tx FIFO. **Value** / **Description** 0x1 Issue Stop 0x0 Do Not Issue Stop	`WO`	`0x0`

Bit	Name	Description	Access	Reset
8	cmd	This bit controls whether a read or a write is performed. This bit does not control the direction when the I2C acts as a slave. It controls only the direction when it acts as a master. When a command is entered in the TX FIFO, this bit distinguishes the write and read commands. In slave-receiver mode, this bit is a 'don't care' because writes to this register are not required. In slave-transmitter mode, a '0' indicates that the CPU data is to be transmitted. When programming this bit, you should remember the following: attempting to perform a read operation after a General Call command has been sent results in a tx_abrt interrupt (bit 6 of the Raw Intr Status Register), unless bit 11 special in the Target Address Register has been cleared. If a '1' is written to this bit after receiving a RD_REQ interrupt, then a tx_abrt interrupt occurs. NOTE: It is possible that while attempting a master I2C read transfer on I2C, a RD_REQ interrupt may have occurred simultaneously due to a remote I2C master addressing I2C. In this type of scenario, I2C ignores the Data Cmd write, generates a tx_abrt interrupt, and waits to service the RD_REQ interrupt. **Value** **Description** 0x1 Master Read 0x0 Master Write	WO	0x0
7:0	dat	This Field contains the data to be transmitted or received on the I2C bus. If you are writing to these bits and want to perform a read, bits 7:0 (dat) are ignored by the I2C. However, when you read from this register, these bits return the value of data received on the I2C interface.	RW	0x0

ic_ss_scl_hcnt

This register sets the SCL clock high-period count for standard speed.

ic_fs_scl_lcnt Fields

Bit	Name	Description	Access	Reset
15:0	ic_fs_scl_lcnt	This register must be set before any I2C bus transaction can take place to ensure proper I/O timing. This field sets the SCL clock low period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. This register can be written only when the I2C interface is disabled, which corresponds to the Enable Register being set to 0. Writes at other times have no effect.The minimum valid value is 8; hardware prevents values less than this being written, and if attempted results in 8 being set.	RW	0x82

ic_intr_stat

Each bit in this register has a corresponding mask bit in the Interrupt Mask Register. These bits are cleared by reading the matching Interrupt Clear Register. The unmasked raw versions of these bits are available in the Raw Interrupt Status Register.

Module Instance	Base Address	Register Address

ic_intr_stat Fields

Bit	Name	Description	Access	Reset
11	`r_gen_call`	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling I2C or when the CPU reads bit 0 of the ic_clr_gen_call register. I2C stores the received data in the Rx buffer.	RO	0x0
10	`r_start_det`	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RO	0x0
9	`r_stop_det`	Indicates whether a STOP condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RO	0x0
8	`r_activity`	This bit captures I2C activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C - Reading the ic_clr_activity register - Reading the ic_clr_intr register - I2C reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus.	RO	0x0
7	`r_rx_done`	When the I2C is acting as a slave-transmitter, this bit is set to 1, if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done.	RO	0x0
6	`r_tx_abrt`	This bit indicates if I2C, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'.When this bit is set to 1, the ic_tx_abrt_source register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register ic_clr_tx_abrt is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface.	RO	0x0

Bit	Name	Description	Access	Reset
5	`r_rd_req`	This bit is set to 1 when i2c is acting as a slave and another I2C master is attempting to read data from I2C. The I2C holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the ic_clr_rd_req register.	RO	0x0
4	`r_tx_empty`	This bit is set to 1 when the transmit buffer is at or below the threshold value set in the ic_tx_tl register. It is automatically cleared by hardware when the buffer level goes above the threshold. When the ic_enable bit 0 is 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer activity, this bit is set to 0.	RO	0x0
3	`r_tx_over`	Set during transmit if the transmit buffer is filled to 64 and the processor attempts to issue another I2C command by writing to the Data and Command Register. When the module is disabled, this bit keeps its level until the master or slave state machines goes into idle, then interrupt is cleared.	RO	0x0
2	`r_rx_full`	Set when the receive buffer reaches or goes above the Receive FIFO Threshold Value(rx_tl). It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled, Bit [0] of the Enable Register set to 0, the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the Enable Register Bit 0 is programmed with a 0, regardless of the activity that continues.	RO	0x0
1	`r_rx_over`	Set if the receive buffer is completely filled to 64 and an additional byte is received from an external I2C device. The I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled, Enable Register bit[0] is set to 0 this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RO	0x0

Bit	Name	Description	Access	Reset
0	r_rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the Tx Rx Data and Command Register. If the module is disabled, Enable Register is set to 0, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RO	0x0

ic_intr_mask

These bits mask their corresponding interrupt status bits.

ic_intr_mask Fields

Bit	Name	Description	Access	Reset
11	m_gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling I2C or when the CPU reads bit 0 of the ic_clr_gen_call register. I2C stores the received data in the Rx buffer.	RW	0x1
10	m_start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RW	0x0

Bit	Name	Description	Access	Reset
9	m_stop_det	Indicates whether a STOP condition has occurred on the I2C interface regardless of whether i2c is operating in slave or master mode.	RW	0x0
8	m_activity	This bit captures i2c activity and stays set until it is cleared. There are four ways to clear it: - Disabling the i2c - Reading the ic_clr_activity register - Reading the ic_clr_intr register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus.	RW	0x0
7	m_rx_done	When the I2C is acting as a slave-transmitter, this bit is set to 1, if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done.	RW	0x1
6	m_tx_abrt	This bit indicates if I2C, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the ic_tx_abrt_source register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register ic_clr_tx_abrt is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface.	RW	0x1
5	m_rd_req	This bit is set to 1 when I2C is acting as a slave and another I2C master is attempting to read data from I2C. The I2C holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the ic_data_cmd register. This bit is set to 0 just after the processor reads the ic_clr_rd_req register.	RW	0x1

Bit	Name	Description	Access	Reset
4	`m_tx_empty`	This bit is set to 1 when the transmit buffer is at or below the threshold value set in the ic_tx_tl register. It is automatically cleared by hardware when the buffer level goes above the threshold. When the ic_enable bit 0 is 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer activity, then this bit is set to 0.	`RW`	`0x1`
3	`m_tx_over`	Set during transmit if the transmit buffer is filled to 64 and the processor attempts to issue another I2C command by writing to the ic_data_cmd register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	`RW`	`0x1`
2	`m_rx_full`	Set when the receive buffer reaches or goes above the RX_TL threshold in the ic_rx_tl register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled ic_enable[0]=0, the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the ic_enable bit 0 is programmed with a 0, regardless of the activity that continues.	`RW`	`0x1`
1	`m_rx_over`	Set if the receive buffer is completely filled to 64 and an additional byte is received from an external I2C device. The I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled ic_enable[0]=0, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	`RW`	`0x1`
0	`m_rx_under`	Set if the processor attempts to read the receive buffer when it is empty by reading from the ic_data_cmd register. If the module is disabled ic_enable[0]=0, this bit keeps its level until the master or slave state machines go into idle, and then this interrupt is cleared.	`RW`	`0x1`

ic_raw_intr_stat

Unlike the ic_intr_stat register, these bits are not masked so they always show the true status of the I2C.

ic_raw_intr_stat Fields

Bit	Name	Description	Access	Reset
11	gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling I2C or when the CPU reads bit 0 of the ic_clr_gen_call register. I2C stores the received data in the Rx buffer.	RO	0x0
10	start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RO	0x0
9	stop_det	Indicates whether a STOP condition has occurred on the I2C interface regardless of whether I2C is operating in slave or master mode.	RO	0x0
8	activity	This bit captures i2c activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C - Reading the ic_clr_activity register - Reading the ic_clr_intr register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the i2c module is idle, this bit remains set until cleared, indicating that there was activity on the bus.	RO	0x0
7	rx_done	When the I2C is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done.	RO	0x0

Bit	Name	Description	Access	Reset
6	tx_abrt	This bit indicates if I2C, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABRT_SOURCE register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register ic_clr_tx_abrt is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface.	RO	0x0
5	rd_req	This bit is set to 1 when I2C is acting as a slave and another I2C master is attempting to read data from I2C. The i2c holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the ic_data_cmd register. This bit is set to 0 just after the processor reads the ic_clr_rd_req register.	RO	0x0
4	tx_empty	This bit is set to 1 when the transmit buffer is at or below the threshold value set in the ic_tx_tl register. It is automatically cleared by hardware when the buffer level goes above the threshold. When the IC_ENABLE bit 0 is 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer activity, then this bit is set to 0.	RO	0x0
3	tx_over	Set during transmit if the transmit buffer is filled to 64 and the processor attempts to issue another I2C command by writing to the ic_data_cmd register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RO	0x0
2	rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the ic_rx_tl register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled ic_enable[0]=0, the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the ic_enable bit 0 is programmed with a 0, regardless of the activity that continues.	RO	0x0

Bit	Name	Description	Access	Reset
1	`rx_over`	Set if the receive buffer is completely filled to 64 and an additional byte is received from an external I2C device. The I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled ic_enable[0]=0), this bit keeps its level until the master or slave state machines go into then, this interrupt is cleared.	RO	0x0
0	`rx_under`	Set if the processor attempts to read the receive buffer when it is empty by reading from the ic_data_cmd register. If the module is disabled ic_enable[0]=0, this bit keeps its level until the master or slave state machines go into idle, then this interrupt is cleared.	RO	0x0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														txabort RW 0x0	enable RW 0x0

ic_enable Fields

Bit	Name	Description	Access	Reset
1	`txabort`	Write 1 does a TX abort. Self cleared on abort completion	RW	0x0
0	`enable`	Controls whether the I2C is enabled. Software can disable I2C while it is active. However, it is important that care be taken to ensure that I2C is disabled properly. When the I2C is disabled, the following occurs: The TX FIFO and RX FIFO get flushed. Status bits in the IC_INTR_STAT register are still active until I2C goes into IDLE state. If the module is transmitting, it stops as well as deletes the contents of the transmit buffer after the current transfer is complete. If the module is receiving, the I2C stops the current transfer at the end of the current byte and does not acknowledge the transfer. The l4_sp_clk synchronizes pclk and ic_clk. The register ic_enable_status is added to allow software to determine when the hardware has completely shutdown in response to the IC_ENABLE register being set from 1 to 0. Only one register is required to be monitored. Procedure for Disabling I2C 1. Define a timer interval (ti2c_poll) equal to the 10 times the signaling period for the highest I2C transfer speed used in the system and supported by I2C. For example, if the highest I2C transfer mode is 400 kb/s, then this ti2c_poll is 25us. 2. Define a maximum time-out parameter, MAX_T_POLL_COUNT, such that if any repeated polling operation exceeds this maximum value, an error is reported. 3. Execute a blocking thread/process/function that prevents any further I2C master transactions to be started by software, but allows any pending transfers to be completed. 4. The variable POLL_COUNT is initialized to zero. 5. Set IC_ENABLE to 0. 6. Read the IC_ENABLE_STATUS register and test the IC_EN bit (bit 0). Increment POLL_COUNT by one. If POLL_COUNT >= MAX_T_POLL_COUNT, exit with the relevant error code. 7. If IC_ENABLE_STATUS[0] is 1, then sleep for ti2c_poll and proceed to the previous step. Otherwise, exit with a relevant success code. **Value** **Description** 0x0 Disables i2c. TX and RX FIFOs are held in an erased state 0x1 Enables i2c. Software can disable i2c while it is active	RW	0x0

ic_status

This is a read-only register used to indicate the current transfer status and FIFO status. The status register may be read at any time. None of the bits in this register request an interrupt.When the I2C is disabled by writing 0 in bit 0 of the ic_enable register: - Bits 1 and 2 are set to 1 - Bits 3 and 4 are set to 0 When the master or slave state machines goes to idle - Bits 5 and 6 are set to 0

ic_tx_abrt_source

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the ic_clr_tx_abrt register or the ic_clr_intr register is read. To clear Bit 9, the source of the abrt_sbyte_norstrt must be fixed first; RESTART must be enabled (ic_con[5]=1), the special bit must be cleared (ic_tar[11]), or the gc_or_start bit must be cleared (ic_tar[10]). Once the source of the abrt_sbyte_norstrt is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the abrt_sbyte_norstrt is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

ic_tx_abrt_source Fields

Bit	Name	Description	Access	Reset
15	abrt_slvrd_intx	When the processor side responds to a slave mode request for data to be transmitted to a remote master and user writes a 1 in CMD (bit 8) of IC_DATA_CMD register. Role of I2C: Slave-Transmitter	RW	0x0
14	abrt_slv_arblost	Slave lost the bus while transmitting data to a remote master. IC_TX_ABRT_SOURCE[12] is set at the same time. Note: Even though the slave never 'owns' the bus, something could go wrong on the bus. This is a fail safe check. For instance, during a data transmission at the low-to-high transition of SCL, if what is on the data bus is not what is supposed to be transmitted, then i2c no longer own the bus. Role of I2C: Slave-Transmitter	RW	0x0
13	abrt_slvflush_txfifo	Slave has received a read command and some data exists in the TX FIFO so the slave issues a TX_ABRT interrupt to flush old data in TX FIFO. Role of I2C: Slave-Transmitter	RW	0x0

Bit	Name	Description	Access	Reset
12	arb_lost	Master has lost arbitration, or if IC_TX_ABRT_SOURCE[14] is also set, then the slave transmitter has lost arbitration. Note: I2C can be both master and slave at the same time. Role of i2c: Master-Transmitter or Slave-Transmitter	RW	0x0
11	abrt_master_dis	User tries to initiate a Master operation with the Master mode disabled. Role of I2C: Master-Transmitter or Master-Receiver	RW	0x0
10	abrt_10b_rd_norstrt	The restart is disabled (ic_restart_en bit (ic_con[5]) =0) and the master sends a read command in 10-bit addressing mode. Role of I2C: Master-Receiver	RW	0x0
9	abrt_sbyte_norstrt	To clear Bit 9, the source of then abrt_sbyte_norstrt must be fixed first; restart must be enabled (ic_con[5]=1), the SPECIAL bit must be cleared (ic_tar[11]), or the GC_OR_START bit must be cleared (ic_tar[10]). Once the source of the abrt_sbyte_norstrt is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the abrt_sbyte_norstrt is not fixed before attempting to clear this bit, bit 9 clears for one cycle and then gets reasserted. 1: The restart is disabled (IC_RESTART_EN bit (ic_con[5]) =0) and the user is trying to send a START Byte. Role of I2C: Master	RW	0x0
8	abrt_hs_norstrt	The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the user is trying to use the master to transfer data in High Speed mode. Role of i2c: Master-Transmitter or Master-Receiver	RW	0x0
7	abrt_sbyte_ackdet	Master has sent a START Byte and the START Byte was acknowledged (wrong behavior). Role of i2c: Master	RW	0x0
6	abrt_hs_ackdet	Master is in High Speed mode and the High Speed Master code was acknowledged (wrong behavior). Role of i2c: Master	RW	0x0
5	abrt_gcall_read	i2c in master mode sent a General Call but the user programmed the byte following the General Call to be a read from the bus (IC_DATA_CMD[9] is set to 1). Role of i2c: Master-Transmitter	RW	0x0
4	abrt_gcall_noack	i2c in master mode sent a General Call and no slave on the bus acknowledged the General Call. Role of i2c: Master-Transmitter	RW	0x0

Bit	Name	Description	Access	Reset
3	`abrt_txdata_noack`	This is a master-mode only bit. Master has received an acknowledgement for the address, but when it sent data byte(s) following the address, it did not receive an acknowledge from the remote slave(s). Role of i2c: Master-Transmitter	RW	0x0
2	`abrt_10addr2_noack`	Master is in 10-bit address mode and the second address byte of the 10-bit address was not acknowledged by any slave. Role of i2c: Master-Transmitter or Master-Receiver	RW	0x0
1	`abrt_10addr1_noack`	Master is in 10-bit address mode and the first 10-bit address byte was not acknowledged by any slave. Role of i2c: Master-Transmitter or Master-Receiver	RW	0x0
0	`abrt_7b_addr_noack`	Master is in 7-bit addressing mode and the address sent was not acknowledged by any slave. Role of i2c: Master-Transmitter or Master-Receiver	RW	0x0

ic_slv_data_nack_only

The register is used to generate a NACK for the data part of a transfer when i2c is acting as a slave-receiver.

ic_dma_rdlr Fields

Bit	Name	Description	Access	Reset
5:0	dmardl	This bit field controls the level at which a DMA request is made by the receive logic. The watermark level \= DMARDL+1; that is, dma_rx_req is generated when the number of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE =1. For instance, when DMARDL is 0, then dma_rx_req is asserted when or more data entries are present in the receive FIFO.	RW	0x0

ic_sda_setup

This register controls the amount of time delay (in terms of number of l4_sp_clk clock periods) introduced in the rising edge of SCL relative to SDA changing by holding SCL low when I2C services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2. Note: The length of setup time is calculated using [(IC_SDA_SETUP - 1) * (l4_sp_clk)], so if the user requires 10 l4_sp_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the I2C when operating as a slave transmitter.

0	`ack_gen_call`	When an ACK is asserted, (by asserting i2c_out_data) when it receives a General call. Otherwise, i2c responds with a NACK (by negating i2c_out_data). **Value** **Description** 0x0 I2C responds with a NACK 0x1 I2C responds with an ACK	RW	0x1

ic_enable_status

This register is used to report the i2c hardware status when the IC_ENABLE register is set from 1 to 0; that is, when i2c is disabled. If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1. If IC_ENABLE has been set to 0, bits 2:1 are only valid as soon as bit 0 is read as '0'. Note: When ic_enable has been written with '0' a delay occurs for bit 0 to be read as '0' because disabling the i2c depends on I2C bus activities.

Module Instance	Base Address	Register Address

ic_enable_status Fields

Bit	Name	Description	Access	Reset
2	`slv_rx_data_lost`	This bit indicates if a Slave-Receiver operation has been aborted with at least one data byte received from an I2C transfer due to the setting of IC ENABLE from 1 to 0. When read as 1, i2c is deemed to have been actively engaged in an aborted I2C transfer (with matching address) and the data phase of the I2C transfer has been entered, even though a data byte has been responded with a NACK. NOTE: If the remote I2C master terminates the transfer with a STOP condition before the i2c has a chance to NACK a transfer, and ic_enable has been set to 0, then this bit is also set to 1. When read as 0, i2c is deemed to have been disabled without being actively involved in the data phase of a Slave-Receiver transfer. NOTE: The CPU can safely read this bit when IC_EN (bit 0) is read as 0.	RO	0x0
1	`slv_disabled_while_busy`	This bit indicates if a potential or active Slave operation has been aborted due to the setting of the ic_enable register from 1 to 0. This bit is set when the CPU writes a 0 to the ic_enable register while: (a) I2C is receiving the address byte of the Slave-Transmitter operation from a remote master; OR, (b) address and data bytes of the Slave-Receiver operation from a remote master. When read as 1, I2C is deemed to have forced a NACK during any part of an I2C transfer, irrespective of whether the I2C address matches the slave address set in i2c (IC_SAR register) OR if the transfer is completed before IC_ENABLE is set to 0 but has not taken effect. NOTE: If the remote I2C master terminates the transfer with a STOP condition before the i2c has a chance to NACK a transfer, and IC_ENABLE has been set to 0, then this bit will also be set to 1. When read as 0, i2c is deemed to have been disabled when there is master activity, or when the I2C bus is idle. NOTE: The CPU can safely read this bit when IC_EN (bit 0) is read as 0.	RO	0x0
0	`ic_en`	This bit always reflects the value driven on the output port ic_en. Not used in current application. When read as 1, i2c is deemed to be in an enabled state. When read as 0, i2c is deemed completely inactive. NOTE: The CPU can safely read this bit anytime. When this bit is read as 0, the CPU can safely read slv_rx_data_lost (bit 2) and slv_disabled_while_busy (bit 1).	RO	0x0

ic_fs_spklen

This register is used to store the duration, measured in ic_clk cycles, of the longest spike that is filtered out by the spike suppression logic when the component is operating in SS or FS modes.

UART Controller 21

2014.06.30

cv_54021 Subscribe Send Feedback

The hard processor system (HPS) provides two UART controllers for asynchronous serial communication. The UART controllers are based on an industry standard 16550 UART controller. The UART controllers are instances of the Synopsys® DesignWare® APB Universal Asynchronous Receiver/ Transmitter (DW_apb_uart) peripheral.[44]

UART Controller Features

The UART controller provides the following functionality and features:

- Programmable character properties, such as number of data bits per character, optional parity bits, and number of stop bits †
- Line break generation and detection †
- Direct memory access (DMA) controller interface
- Prioritized interrupt identification †
- Programmable baud rate
- False start bit detection †
- Automatic flow control mode per 16750 standard †
- Internal loopback mode support
- 128-byte transmit and receive FIFO buffers
  - FIFO buffer status registers †
  - FIFO buffer access mode (for FIFO buffer testing) enables write of receive FIFO buffer by master and read of transmit FIFO buffer by master †
- Shadow registers reduce software overhead and provide programmable reset †
- Transmitter holding register empty (THRE) interrupt mode †

UART Controller Block Diagram and System Integration

Figure 21-1: UART Block Diagram

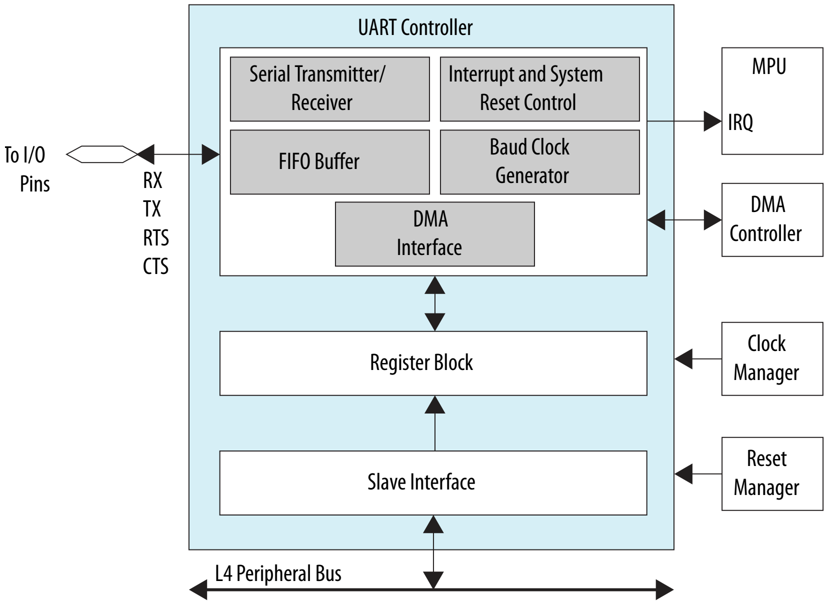

Table 21-1: UART Controller Block Descriptions

Block	Description
Slave interface	Slave interface between the component and L4 peripheral bus.
Register block	Provides main UART control, status, and interrupt generation functions.†
FIFO buffer	Provides FIFO buffer control and storage. †
Baud clock generator	Generates the transmitter and receiver baud clock. With a reference clock of 100 MHz, the UART controller supports transfer rates of 95 baud to 6.25 Mbaud. This supports communication with all known 16550 devices. The baud rate is controlled by programming the interrupt enable or divisor latch high (`IER_DLH`) and receive buffer, transmit holding, or divisor latch low (`RBR_THR_DLL`) registers.

Block	Description
Serial transmitter	Converts parallel data written to the UART into serial data and adds all additional bits, as specified by the control register, for transmission. This makeup of serial data, referred to as a character, exits the block in serial UART. †
Serial receiver	Converts the serial data character (as specified by the control register) received in the UART format to parallel form. Parity error detection, framing error detection and line break detection is carried out in this block. †
DMA interface	The UART controller includes a DMA controller interface to indicate when received data is available or when the transmit FIFO buffer requires data. The DMA requires two channels, one for transmit and one for receive. The UART controller supports single and burst transfers. You can use DMA in FIFO buffer and non-FIFO buffer mode.

DMA Controller on page 16-1
For more information, refer to this *DMA Controller* chapter.

Functional Description of the UART Controller

The HPS UART is based on an industry-standard 16550 UART. The UART supports serial communication with a peripheral, modem (data carrier equipment), or data set. The master (CPU) writes data over the slave bus to the UART. The UART converts the data to serial format and transmits to the destination device. The UART also receives serial data and stores it for the master (CPU). †

The UART's registers control the character length, baud rate, parity generation and checking, and interrupt generation. The UART's single interrupt output signal is supported by several prioritized interrupt types that trigger assertion. You can separately enable or disable each of the interrupt types with the control registers. †

FIFO Buffer Support

The UART controller includes 128-byte FIFO buffers to buffer transmit and receive data. FIFO buffer access mode allows the master to write the receive FIFO buffer and to read the transmit FIFO buffer for test purposes. FIFO buffer access mode is enabled with the FIFO access register (FAR). Once enabled, the control portions of the transmit and receive FIFO buffers are reset and the FIFO buffers are treated as empty. †

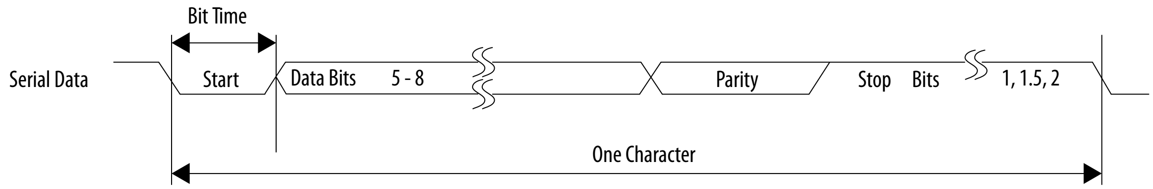
When FIFO buffer access mode is enabled, you can write data to the transmit FIFO buffer as normal; however, no serial transmission occurs in this mode and no data leaves the FIFO buffer. You can read back the data that is written to the transmit FIFO buffer with the transmit FIFO read (TFR) register. The TFR register provides the current data at the top of the transmit FIFO buffer. †

Similarly, you can also read data from the receive FIFO buffer in FIFO buffer access mode. Since the normal operation of the UART is halted in this mode, you must write data to the receive FIFO buffer to read it back. The receive FIFO write (`RFW`) register writes data to the receive FIFO buffer. The upper two bits of the 10-bit register write framing errors and parity error detection information to the receive FIFO buffer. Bit 9 of `RFW` indicates a framing error and bit 8 of `RFW` indicates a parity error. Although you cannot read these bits back from the receive buffer register, you can check the bits by reading the line status register (`LSR`), and by checking the corresponding bits when the data in question is at the top of the receive FIFO buffer. †

UART(RS232) Serial Protocol

Because the serial communication between the UART controller and the selected device is asynchronous, additional bits (start and stop) are added to the serial data to indicate the beginning and end. Utilizing these bits allows two devices to be synchronized. This structure of serial data accompanied by start and stop bits is referred to as a character, as shown in below.†

Figure 21-2: Serial Data Format



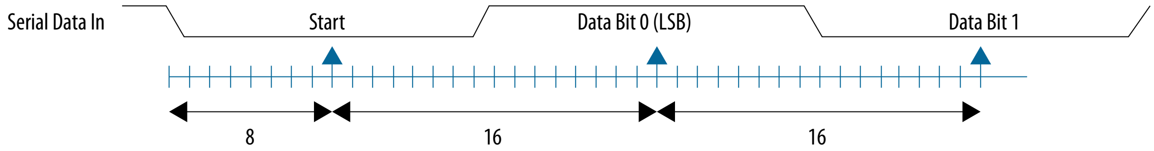
An additional parity bit may be added to the serial character. This bit appears after the last data bit and before the stop bit(s) in the character structure to provide the UART controller with the ability to perform simple error checking on the received data.†

The Control Register is used to control the serial character characteristics. The individual bits of the data word are sent after the start bit, starting with the least- significant bit (LSB). These are followed by the optional parity bit, followed by the stop bit(s), which can be 1, 1.5 or 2.†

All the bits in the transmission (with exception to the half stop bit when 1.5 stop bits are used) are transmitted for exactly the same time duration. This is referred to as a Bit Period or Bit Time. One Bit Time equals to 16 baud clocks. To ensure stability on the line, the receiver samples the serial input data at approximately the midpoint of the Bit Time once the start bit has been detected. As the exact number of baud clocks that each bit was transmitted for is known, calculating the midpoint for sampling is not difficult. That is, every 16 baud clocks after the midpoint sample of the start bit.†

Together with serial input debouncing, this feature also contributes to avoid the detection of false start bits. Short glitches are filtered out by debouncing, and no transition is detected on the line. If a glitch is wide enough to avoid filtering by debouncing, a falling edge is detected. However, a start bit is detected only if the line is sampled low again after half a bit time has elapsed. †

Figure 21-3: Receiver Serial Data Sample Points



The baud rate of the UART controller is controlled by the serial clock and the Divisor Latch Register (DLH and DLL).†

Automatic Flow Control

The UART includes 16750-compatible request-to-send (RTS) and clear-to-send (CTS) serial data automatic flow control mode. You enable automatic flow control with the modem control register (`MCR.AFCE`). †

Automatic RTS mode

Automatic RTS mode becomes active when the following conditions occur: †

- RTS (`MCR.RTS` bit and `MCR.AFCE` bit are both set)
- FIFO buffers are enabled (`FCR.FIFOE` bit is set)

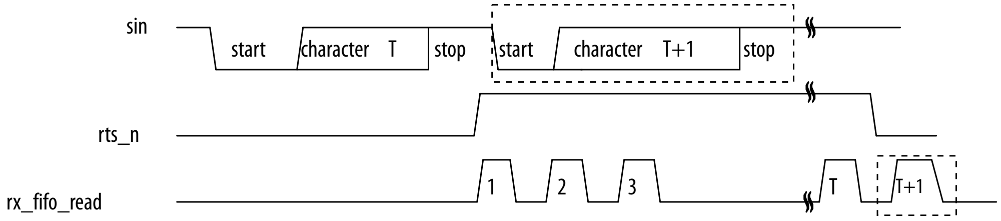
With automatic RTS enabled, the `rts_n` output pin is forced inactive (high) when the FIFO is almost full; where "almost full" refers to two available slots in the FIFO. When `rts_n` is connected to the `cts_n` input pin of another UART device, the other UART stops sending serial data until the receive FIFO buffer has available space (until it is completely empty). †

The selectable receive FIFO buffer threshold values are 1, ¼, ½, and 2 less than full. Because one additional character may be transmitted to the UART after `rts_n` is inactive (due to data already having entered the transmitter block in the other UART), setting the threshold to 2 less than full allows maximum use of the FIFO buffer with a margin of one character. †

Once the receive FIFO buffer is completely emptied by reading the receiver buffer register (`RBR_THR_DLL`), `rts_n` again becomes active (low), signaling the other UART to continue sending data.†

Even when you set the correct MCR bits, if the FIFO buffers are disabled through `FCR.FIFOE`, automatic flow control is also disabled. When auto RTS is not implemented or disabled, `rts_n` is controlled solely by `MCR.RTS`. In the Automatic RTS Timing diagram, the character T is received because `rts_n` is not detected prior to the next character entering the sending UART transmitter. †

Figure 21-4: Automatic RTS Timing



Automatic CTS mode

Automatic CTS mode becomes active when the following conditions occur: †

- AFCE (`MCR.AFCE` bit is set)
- FIFO buffers are enabled (through FIFO buffer control register `IIR_FCR.FIFOE`) bit

When automatic CTS is enabled (active), the UART transmitter is disabled whenever the `cts_n` input becomes inactive (high). This prevents overflowing the FIFO buffer of the receiving UART. †

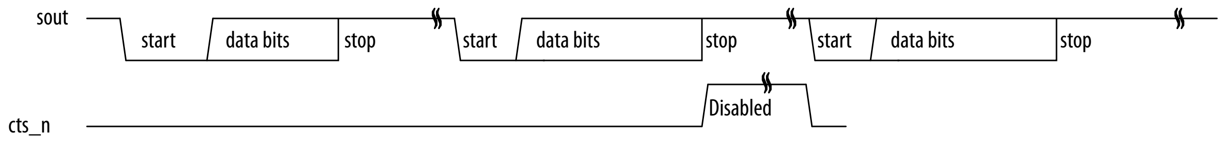
If the `cts_n` input is not deactivated before the middle of the last stop bit, another character is transmitted before the transmitter is disabled. While the transmitter is disabled, you can continue to write and even overflow to the transmit FIFO buffer. †

Automatic CTS mode requires the following sequence:

1. The UART status register are read to verify that the transmit FIFO buffer is full (UART status register `USR.TFNF` set to zero). †
2. The current FIFO buffer level is read via the transmit FIFO level (`TFL`) register. †
3. Programmable THRE interrupt mode must be enabled to access the FIFO buffer full status from the LSR. †

When using the FIFO buffer full status, software can poll this before each write to the transmit FIFO buffer. When the `cts_n` input becomes active (low) again, transmission resumes. If the FIFO buffers are disabled with the `FCR.FIFOE` bit, automatic flow control is also disabled regardless of any other settings. When auto CTS is not implemented or disabled, the transmitter is unaffected by `cts_n`.†

Figure 21-5: Automatic CTS Timing



Interface Pins

Table 21-2: Interface Pins

Pin	Width	Direction	Description
RX	1 bit	Input	Serial Input
TX	1 bit	Output	Serial Output
CTS	1 bit	Input	Clear to send
RTS	1 bit	Output	Request to send

FPGA Routing

Table 21-3: Signals for FPGA Routing

Signal	Width	Direction	Description
uart_rxd	1 bit	Input	Serial input
uart_txd	1 bit	Output	Serial output
uart_cts	1 bit	Input	Clear to send

Signal	Width	Direction	Description
uart_rts	1 bit	Output	Request to send
uart_dsr	1 bit	Input	Data set ready
uart_dcd	1 bit	Input	Data carrier detect
uart_ri	1 bit	Input	Ring indicator
uart_dtr	1 bit	Output	Data terminal ready
uart_out1_n	1 bit	Output	User defined output 1
uart_out2_n	1 bit	Output	User defined output 2

Clocks

The UART controller is connected to the `l4_sp_clk` clock. The clock input is driven by the clock manager.

Related Information

Clock Manager on page 2-1
For more information, refer to the *Clock Manager* chapter.

Resets

The UART controller is connected to the `uart_rst_n` reset signal. The reset manager drives the signal on a cold or warm reset.

Related Information

Reset Manager on page 3-1
For more information, refer to the *Reset Manager* chapter.

Interrupts

The assertion of the UART interrupt output signal occurs when one of the following interrupt types are enabled and active: †

Table 21-4: Interrupt Types and Priority †

Interrupt Type	Priority	Source	Interrupt Reset Control
Receiver line status	Highest	Overrun, parity and framing errors, break condition.	Reading the line status Register.

Interrupt Type	Priority	Source	Interrupt Reset Control
Received data available	Second	Receiver data available (FIFOs disabled) or RCVR FIFO trigger level reached (FIFOs enabled).	Reading the receiver buffer register (FIFOs disabled) or the FIFO drops below the trigger level (FIFOs enabled)
Character timeout indication	Second	No characters in or out of the Receive FIFO during the last 4 character times and there is at least 1 character in it during this Time.	Reading the receiver buffer Register.
Transmit holding register empty	Third	Transmitter holding register empty (Programmable THRE Mode disabled) or Transmit FIFO at or below threshold (Programmable THRE Mode enabled).	Reading the IIR register (if source of interrupt); or, writing into THR (FIFOs or Programmable THRE Mode not enabled) or Transmit FIFO above threshold (FIFOs and Programmable THRE Mode enabled).
Modem Status	Fourth	Clear to send or data set ready or ring indicator or data carrier detect. If auto flow control mode is enabled, a change in CTS (that is, DCTS set) does not cause an interrupt.	Reading the Modem status Register.

You can enable the interrupt types with the interrupt enable register (`IER_DLH`).

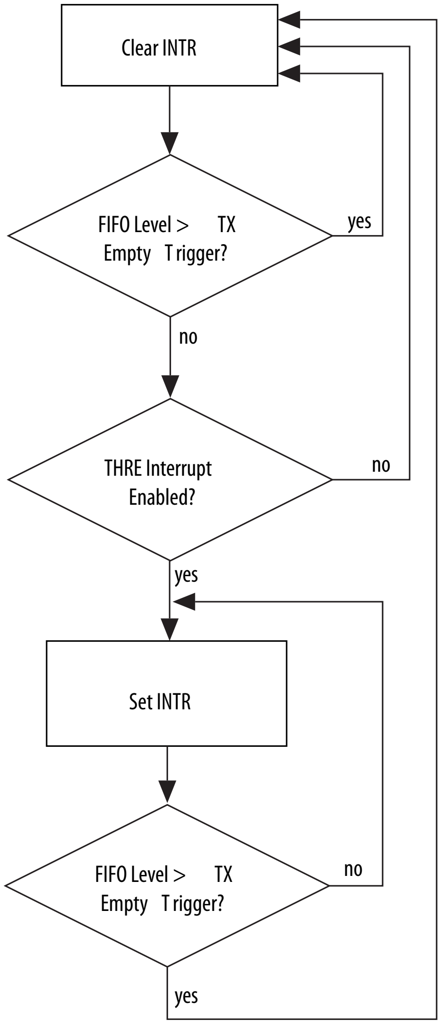
Note: Received Data Available" and "Character Timeout Indication" are enabled by a single bit in the IER_DLH register, because they have the same priority.

Once an interrupt is signaled, you can determine the interrupt source by reading the Interrupt Identity Register (IIR).

Programmable THRE Interrupt

The UART has a programmable THRE interrupt mode to increase system performance. You enable the programmable THRE interrupt mode with the interrupt enable register (`IER_DLH.PTIME`). When the THRE mode is enabled, THRE interrupts and the `dma_tx_req` signal are active at and below a programmed transmit FIFO buffer empty threshold level, as shown in the flowchart. †

Figure 21-6: Programmable THRE Interrupt



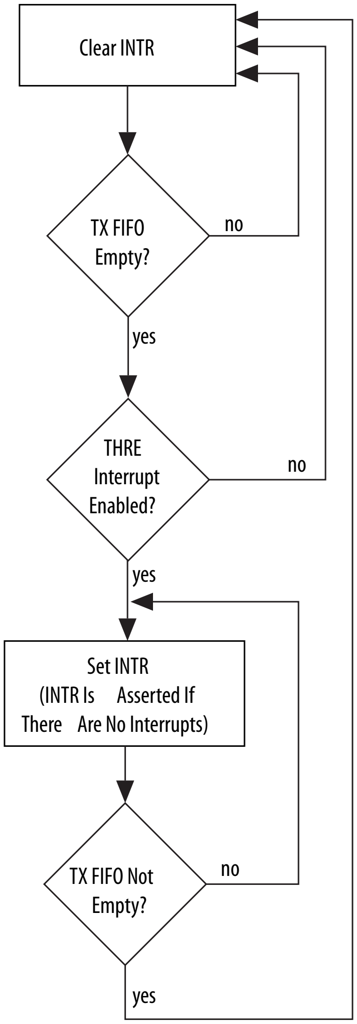
Clear INTR
FIFO Level > TX Empty Trigger?
yes
no
THRE Interrupt Enabled?
no
yes
Set INTR
FIFO Level > TX Empty Trigger?
no
yes

The threshold level is programmed into `FCR.TET`. The available empty thresholds are empty, 2, ¼, and ½. The optimum threshold value depends on the system's ability to begin a new transmission sequence in a timely manner. However, one of these thresholds should prove optimum in increasing system performance by preventing the transmit FIFO buffer from running empty.

In addition to the interrupt change, line status register (`LSR.THRE`) also switches from indicating that the transmit FIFO buffer is empty, to indicating that the FIFO buffer is full. This change allows software to fill the FIFO buffer for each transmit sequence by polling `LSR.THRE` before writing another character. This directs the UART to fill the transmit FIFO buffer whenever an interrupt occurs and there is data to transmit, instead of waiting until the FIFO buffer is completely empty. Waiting until the FIFO buffer is empty reduces performance whenever the system is too busy to respond immediately. You can increase system efficiency when this mode is enabled in combination with automatic flow control.

When not selected or disabled, THRE interrupts and `LSR.THRE` function normally, reflecting an empty THR or FIFO buffer.

Figure 21-7: Interrupt Generation without Programmable THRE Interrupt Mode



DMA Controller Operation

The UART controller includes a DMA controller interface to indicate when the receive FIFO buffer data is available or when the transmit FIFO buffer requires data. The DMA requires two channels, one for transmit and one for receive. The UART controller supports both single and burst transfers.

The FIFO buffer depth (`FIFO_DEPTH`) for both the RX and TX buffers in the UART controller is 128 entries.

Related Information

DMA Controller on page 16-1
For more information, refer to this *DMA Controller* chapter.

Transmit FIFO Underflow

During UART serial transfers, transmit FIFO requests are made to the DMA controller whenever the number of entries in the transmit FIFO is less than or equal to the decoded level of the Transmit Empty

Trigger (TET) field in the FIFO Control Register (FCR), also known as the watermark level. The DMA controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length. †

Data should be fetched from the DMA often enough for the transmit FIFO to perform serial transfers continuously, that is, when the FIFO begins to empty, another DMA request should be triggered. Otherwise, the FIFO will run out of data (underflow) causing a STOP to be inserted on the UART bus. To prevent this condition, you must set the watermark level correctly. †

Related Information

DMA Controller on page 16-1
For more information, refer to this *DMA Controller* chapter.

Transmit Watermark Level

Consider the example where the following assumption is made: †

DMA burst length = `FIFO_DEPTH` - decoded watermark level of `IIR_FCR.TET` †

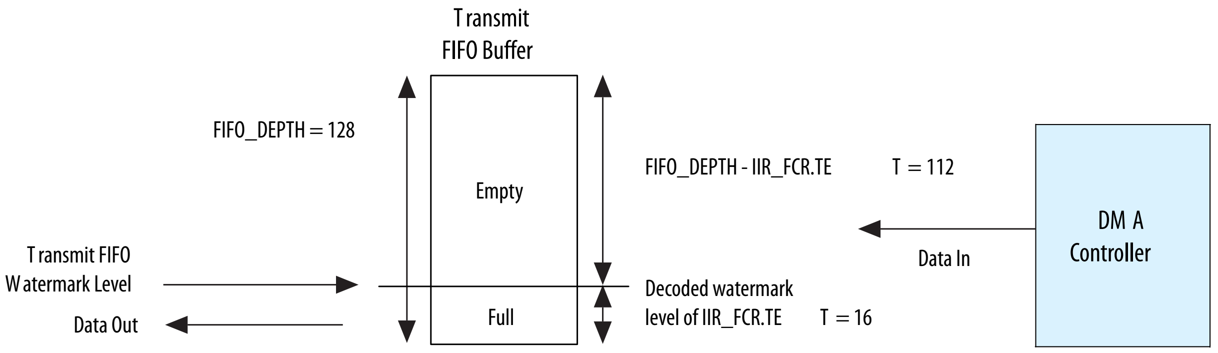
Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO. Consider the following two different watermark level settings: †

IIR_FCR.TET = 1

`IIR_FCR.TET` = 1 decodes to a watermark level of 16.

- Transmit FIFO watermark level = decoded watermark level of `IIR_FCR.TET` = 16 †
- DMA burst length = `FIFO_DEPTH` - decoded watermark level of `IIR_FCR.TET` = 112 †
- UART transmit `FIFO_DEPTH` = 128 †
- Block transaction size =R** 448†

Figure 21-8: Transmit FIFO Watermark Level = 16



The number of burst transactions needed equals the block size divided by the number of data items per burst:

Block transaction size/DMA burst length = 448/112 = 4

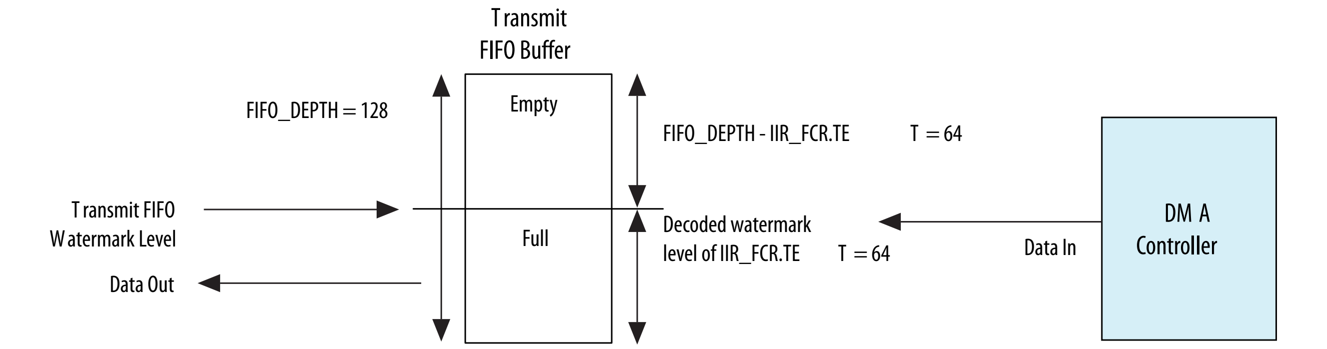
The number of burst transactions in the DMA block transfer is 4. But the watermark level, decoded level of `IIR_FCR.TET`, is quite low. Therefore, the probability of transmit underflow is high where the UART serial transmit line needs to transmit data, but there is no data left in the transmit FIFO. This occurs because the DMA has not had time to service the DMA request before the FIFO becomes empty.

IIR_FCR.TET = 3

`IIR_FCR.TET` = 3 decodes to a watermark level of 64.

- Transmit FIFO watermark level = decoded watermark level of `IIR_FCR.TET` = 64 †
- DMA burst length = `FIFO_DEPTH` - decoded watermark level of `IIR_FCR.TET` = 64†
- UART transmit `FIFO_DEPTH` = 128 †
- Block transaction size = 448 †

Figure 21-9: Transmit FIFO Watermark Level = 64



Number of burst transactions in block: †

Block transaction size/DMA burst length = 448/64 = 7 †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, decoded level of `IIR_FCR.TET`, is high. Therefore, the probability of UART transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the UART transmit FIFO becomes empty. †

Thus, the second case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case. †

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the UART transmits data to the rate at which the DMA can respond to destination burst requests. †

Transmit FIFO Overflow

Setting the DMA burst length to a value greater than the watermark level that triggers the DMA request might cause overflow when there is not enough space in the transmit FIFO to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

DMA burst length <= `FIFO_DEPTH` - decoded watermark level of `IIR_FCR.TET`

In case 2: decoded watermark level of `IIR_FCR.TET` = 64, the amount of space in the transmit FIFO at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO may be full, but not overflowed, at the completion of the burst transaction. †

Therefore, for optimal operation, DMA burst length should be set at the FIFO level that triggers a transmit DMA request; that is: †

DMA burst length = `FIFO_DEPTH` - decoded watermark level of `IIR_FCR.TET`

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO will not be full at the end of a DMA burst transfer if the UART controller has successfully transmitted one data item or more on the UART serial transmit line during the transfer. †

Receive FIFO Overflow

During UART serial transfers, receive FIFO requests are made to the DMA whenever the number of entries in the receive FIFO is at or above the decoded level of Receive Trigger (`RT`) field in the FIFO Control Register (`IIR_FCR`). This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO. †

Data should be fetched by the DMA often enough for the receive FIFO to accept serial transfers continuously, that is, when the FIFO begins to fill, another DMA transfer is requested. Otherwise the FIFO will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

Receive Watermark Level

Similar to choosing the transmit watermark level described earlier, the receive watermark level, decoded watermark level of `IIR_FCR.RT`, should be set to minimize the probability of overflow, as shown in the Receive FIFO Buffer diagram. It is a tradeoff between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Receive FIFO Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

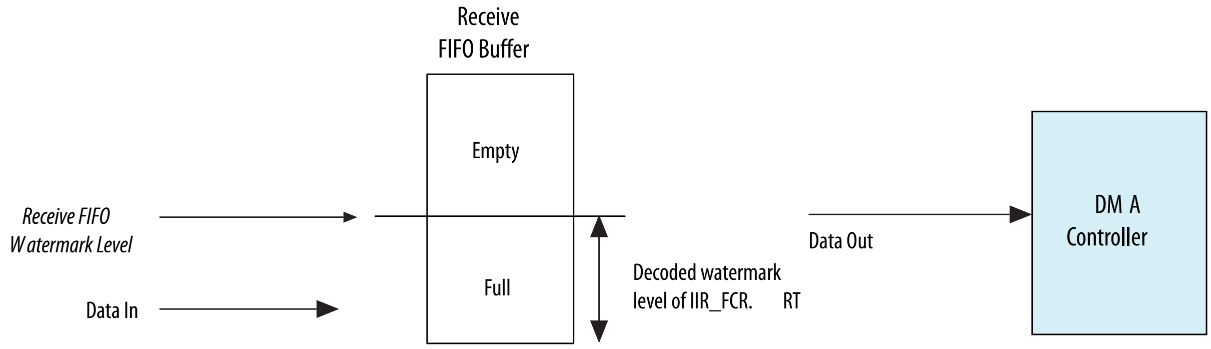
DMA burst length = decoded watermark level of `IIR_FCR.RT` + 1

If the number of data items in the receive FIFO is equal to the source burst length at the time of the burst request is made, the receive FIFO may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, decoded watermark level of `IIR_FCR.RT`. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can avoid underflow and improve bus utilization. †

The receive FIFO will not be empty at the end of the source burst transaction if the UART controller has successfully received one data item or more on the UART serial receive line during the burst. †

Figure 21-10: Receive FIFO Buffer



UART Controller Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

- UART Module 0
- UART Module 1

rbr_thr_dll Fields

Bit	Name	Description	Access	Reset
7:0	value	Receive Buffer Register: This register contains the data byte received on the serial input port (uart_rxd). The data in this register is valid only if the Data Ready (bit [0] in the Line Status Register(LSR)) is set to 1. If FIFOs are disabled(bit[0] of Register FCR is set to 0) the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an overrun error. If FIFOs are enabled(bit [0] of Register FCR is set to 1) this register accesses the head of the receive FIFO. If the receive FIFO is full, and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost. An overrun error will also occur. Transmit Holding Register: This register contains data to be transmitted on the serial output port. Data should only be written to the THR when the THR Empty bit [5] of the LSR Register is set to 1. If FIFOs are disabled (bit [0] of Register FCR) is set to 0 and THRE is set to 1, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If FIFO's are enabled bit [0] of Register FCR is set to 1 and THRE is set up to 128 characters of data may be written to the THR before the FIFO is full. Any attempt to write data when the FIFO is full results in the write data being lost. Divisor Latch Low: This register makes up the lower 8-bits of a 16-bit, Read/ write, Divisor Latch register that contains the baud rate divisor for the UART. This register may only be accessed when the DLAB bit [7] of the LCR Register is set to 1. The output baud rate is equal to the serial clock l4_sp_clk frequency divided by sixteen times the value of the baud rate divisor, as follows: baud rate = (serial clock freq) / (16 * divisor) Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications will occur. Also, once the DLL is set, at least 8 l4_sp_clk clock cycles should be allowed to pass before transmitting or receiving data.	RW	0x0

ier_dlh

This is a multi-function register. This register enables/disables receive and transmit interrupts and also controls the most-significant 8-bits of the baud rate divisor. Divisor Latch High Register: This register is accessed when the DLAB bit [7] of the LCR Register is set to 1.Bits[7:0] contain the high order 8-bits of the baud rate divisor.The output baud rate is equal to the serial clock l4_sp_clk frequency divided by sixteen times the value of the baud rate divisor, as follows: baud rate = (serial clock freq) / (16 * divisor): Note that with the Divisor Latch Registers (DLLand DLH) set to zero, the baud clock is disabled and no serial communications will occur. Also, once the DLL is set, at least 8 l4_sp_clk clock cycles should be allowed to pass before transmitting or receiving data. Interrupt Enable Register: This register may only be accessed when the DLAB bit [7] of the LCR Register is set to 0.Allows control of the Interrupt Enables for transmit and receive functions.

Bit	Name	Description	Access	Reset
7:6	rt	This register is configured to implement FIFOs. Bits[7:6], Rx Trigger (or RT): This is used to select the trigger level in the receiver FIFO at which the Received Data Available Interrupt will be generated. In auto flow control mode it is used to determine when the uart_rts_n signal will be de-asserted. It also determines when the uart_dma_rx_req_n signal will be asserted when in certain modes of operation. **Value** — **Description** 0x0 — one character in fifo 0x1 — FIFO 1/4 full 0x2 — FIFO 1/2 full 0x3 — FIFO 2 less than full	WO	0x0
5:4	tet	This is used to select the empty threshold level at which the THRE Interrupts will be generated when the mode is active. It also determines when the uart DMA transmit request signal uart_dma_tx_req_n will be asserted when in certain modes of operation. **Value** — **Description** 0x0 — FIFO empty 0x1 — Two characters in FIFO 0x2 — FIFO 1/4 full 0x3 — FIFO 1/2 full	WO	0x0

Bit	Name	Description	Access	Reset
3	dmam	This determines the DMA signalling mode used for the uart_dma_tx_req_n and uart_dma_rx_req_n output signals when additional DMA handshaking signals are not selected. DMA mode 0 supports single DMA data transfers at a time. In mode 0, the uart_dma_tx_req_n signal goes active low under the following conditions: -When the Transmitter Holding Register is empty in non-FIFO mode. -When the transmitter FIFO is empty in FIFO mode with Programmable THRE interrupt mode disabled. -When the transmitter FIFO is at or below the programmed threshold with Programmable THRE interrupt mode enabled. It goes inactive under the following conditions -When a single character has been written into the Transmitter Holding Register or transmitter FIFO with Programmable THRE interrupt mode disabled. -When the transmitter FIFO is above the threshold with Programmable THRE interrupt mode enabled. DMA mode 1 supports multi-DMA data transfers, where multiple transfers are made continuously until the receiver FIFO has been emptied or the transmit FIFO has been filled. In mode 1 the uart_dma_tx_req_n signal is asserted under the following conditions: -When the transmitter FIFO is empty with Programmable THRE interrupt mode disabled. -When the transmitter FIFO is at or below the programmed threshold with Programmable THRE interrupt mode enabled. **Value** — **Description** 0x0 — Single DMA Transfer Mode 0x1 — Multiple DMA Transfer Mode	WO	0x0
2	xfifor	Resets the control portion of the transmit FIFO and treats the FIFO as empty. This will also de-assert the DMA Tx request and single signals when additional DMA handshaking is used. Note that this bit is 'self-clearing' and it is not necessary to clear this bit. **Value** — **Description** 0x0 — No Reset of Tx FIFO Control 0x1 — Resets Tx FIFO Control	WO	0x0

Bit	Name	Description	Access	Reset
1	rfifor	Resets the control portion of the receive FIFO and treats the FIFO as empty. This will also de-assert the DMA Rxrequest and single signals. Note that this bit is self-clearing' and it is not necessary to clear this bit. **Value** — **Description** 0x0 — No Reset of Rx FIFO Control 0x1 — Resets of Rx FIFO Control	WO	0x0
0	fifoe	Enables/disables the transmit (Tx) and receive (Rx) FIFO's. Whenever the value of this bit is changed both the Tx and Rx controller portion of FIFO's will be reset. **Value** — **Description** 0x0 — FIFOs disabled 0x1 — FIFOs enabled	WO	0x0

lcr Fields

Bit	Name	Description	Access	Reset
7	`dlab`	Used to enable reading and writing of the Divisor Latch register (DLL and DLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers.	`RW`	`0x0`
6	`break`	This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low.	`RW`	`0x0`
4	`eps`	This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic '1's is transmitted or checked. If set to zero, an odd number of logic '1's is transmitted or checked. **Value** — **Description** 0x0 — odd parity 0x1 — even parity	`RW`	`0x0`
3	`pen`	This bit is used to enable and disable parity generation and detection in a transmitted and received data character. **Value** — **Description** 0x0 — parity disabled 0x1 — parity enabled	`RW`	`0x0`
2	`stop`	Number of stop bits. Used to select the number of stop bits per character that the peripheral will transmit and receive.Note that regardless of the number of stop bits selected the receiver will only check the first stop bit. **Value** — **Description** 0x0 — one stop bit 0x1 — 1.5 stop bits when DLS (LCR[1:0]) is zero	`RW`	`0x0`

Bit	Name	Description	Access	Reset
1:0	dls	Data Length Select.Selects the number of data bits per character that the peripheral will transmit and receive. **Value** **Description** 0x0 5 bits 0x1 6 bits 0x2 7 bits 0x3 8 bits	RW	0x0

Bit	Name	Description	Access	Reset
4	`loopback`	This is used to put the UART into a diagnostic mode for test purposes. If UART mode is NOT active, bit [6] of the modem control register MCR is set to zero, data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (uart_dsr_n, uart_cts_n, uart_ri_n, uart_dcd_n) are disconnected and the modem control outputs (uart_dtr_n, uart_rts_n, uart_out1_n, uart_out2_n) are loopedback to the inputs, internally.	`RW`	`0x0`
3	`out2`	This is used to directly control the user-designated uart_out2_n output. The value written to this location is inverted and driven out on uart_out2_n Note: In Loopback mode bit 4 of the modem control register (MCR) is set to one, the uart_out2_n output is held inactive high while the value of this location is internally looped back to an input. **Value** — **Description** 0x0 — uart_out2_n de-asserted (logic 1) 0x1 — uart_out2_n asserted (logic 0)	`RW`	`0x0`
2	`out1`	The value written to this location is inverted and driven out on uart_out1_n pin. Note that in Loopback mode (MCR[4] set to one), the uart_out1_n output is held inactive high while the value of this location is internally looped back to an input. **Value** — **Description** 0x0 — uart_out1_n de-asserted (logic 1) 0x1 — uart_out1_n asserted (logic 0)	`RW`	`0x0`

Bit	Name	Description	Access	Reset
1	rts	This is used to directly control the Request to Send (uart_rts_n) output. The Request to Send (uart_rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the uart_rts_n signal is set low by programming MCR[1] (RTS) to a high. If Auto Flow Control is active (MCR[5] set to one) and FIFO's enable (FCR[0] set to one), the uart_rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (uart_rts_n is inactive high when above the threshold). The uart_rts_n signal will be de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the uart_rts_n output is held inactive high while the value of this location is internally looped back to an input. **Value** / **Description** 0x0 uart_rts_n de-asserted (logic 1) 0x1 uart_rts_n asserted (logic 0)	RW	0x0
0	dtr	This is used to directly control the Data Terminal Ready output. The value written to this location is inverted and driven out on uart_dtr_n, that is: The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that Loopback mode bit [4] of MCR is set to one, the uart_dtr_n output is held inactive high while the value of this location is internally looped back to an input. **Value** / **Description** 0x0 uart_dtr_n de-asserted (logic 1) 0x1 uart_dtr_n asserted (logic 0)	RW	0x0

Bit	Name	Description	Access	Reset
7	rfe	This bit is only relevant when FIFO's are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO. **Value** **Description** 0x0 no error in Rx FIFO 0x1 error in Rx FIFO	RO	0x0
6	temt	If in FIFO mode and FIFO's enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If FIFO's are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty. **Value** **Description** 0x0 Transmit Empty not set 0x1 Transmit Empty set	RO	0x1
5	thre	If THRE mode is disabled (IER[7] set to zero) this bit indicates that the THR or Tx FIFO is empty. This bit is set whenever data is transferred from the THR or Tx FIFO to the transmitter shift register and no new data has been written to the THR or Tx FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If both THRE and FIFOs are enabled, both (IER[7] set to one and FCR[0] set to one respectively), the functionality will indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] thresholdsetting.	RO	0x1

<table>
<tr><th>Bit</th><th>Name</th><th>Description</th><th>Access</th><th>Reset</th></tr>
<tr><td>4</td><td>bi</td><td>This is used to indicate the detection of a break sequence on the serial input data. Set whenever the serial input, sin, is held in a logic 0 state for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. The character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit.</td><td>RO</td><td>0x0</td></tr>
<tr><td>3</td><td>fe</td><td>This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs the UART will try to resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit(LSR[3]) will be set if a break interrupt has occurred, as indicated by a Break Interrupt BIT bit (LSR[4]). Reading the LSR clears the FE bit.
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0x0</td><td>no framing error</td></tr>
<tr><td>0x1</td><td>framing error</td></tr>
</table></td><td>RO</td><td>0x0</td></tr>
<tr><td>2</td><td>pe</td><td>This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. Since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). Reading the LSR clears the PE bit.
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0x0</td><td>no parity error</td></tr>
<tr><td>0x1</td><td>no parity error</td></tr>
</table></td><td>RO</td><td>0x0</td></tr>
</table>

Bit	Name	Description	Access	Reset
1	oe	This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost.Reading the LSR clears the OE bit. **Value** — **Description** 0x0 — no overrun error 0x1 — overrun error	RO	0x0
0	dr	This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. This bit is cleared when the RBR is read in the non-FIFO mode, or when the receiver FIFO is empty, in the FIFO mode. **Value** — **Description** 0x0 — no data ready 0x1 — data ready	RO	0x0

msr

It should be noted that whenever bits 0, 1, 2 or 3 are set to logic one, to indicate a change on the modem control inputs, a modem status interrupt will be generated if enabled via the IER regardless of when the change occurred. Since the delta bits (bits 0, 1, 3) can get set after a reset if their respective modem signals are active (see individual bits for details), a read of the MSR after reset can be performed to prevent unwanted interrupts.

Bit	Name	Description	Access	Reset
7	dcd	This is used to indicate the current state of the modem control line uart_dcd_n. That is this bit is the complement uart_dcd_n. When the Data Carrier Detect input (uart_dcd_n) is asserted it is an indication that the carrier has been detected by the modem or data set. In Loopback Mode (MCR[4] set to one), DCD is the same as MCR[3] (uart_out2). **Value** **Description** 0x0 uart_dcd_n input is de-asserted (logic 1) 0x1 uart_dcd_n input is asserted (logic 0)	RO	0x0
6	ri	This bit is used to indicate the current state of the modem control line uart_ri_n. That is this bit is the complement uart_ri_n. When the Ring Indicator input (uart_ri_n) is asserted it is an indication that a telephone ringing signal has been received by the modem or data set. In Loopback Mode bit [4] of register MCR set to one, RI is the same as bit [2] uart_out1_n of register MCR. **Value** **Description** 0x0 uart_ri_n input is de-asserted (logic 1) 0x1 uart_ri_n input is asserted (logic 0)	RO	0x0

Bit	Name	Description	Access	Reset
5	dsr	This is used to indicate the current state of the modem control line uart_dsr_n. That is this bit is the complement f uart_dsr_n. When the Data Set Ready input (uart_dsr_n) is asserted it is an indication that the modem or data set is ready to establish communications with the uart. In Loopback Mode bit [4] of register MCR is set to one, DSR is the same as bit [0] (DTR) of register MCR. **Value** **Description** 0x0 uart_dsr_n input is de-asserted (logic 1) 0x1 uart_dsr_n input is asserted (logic 0)	RO	0x0
4	cts	This is used to indicate the current state of the modem control line uart_cts_n. That is, this bit is the complement uart_cts_n. When the Clear to Send input (uart_cts_n) is asserted it is an indication that the modem or data set is ready to exchange data with the uart. In Loopback Mode bit [4] of register MCR is set to one, CTS is the same as bit [1] RTS of register MCR. **Value** **Description** 0x0 uart_cts_n input is de-asserted (logic 1) 0x1 uart_cts_n input is asserted (logic 0)	RO	0x0
3	ddcd	This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. Reading the MSR clears the DDCD bit. In Loopback Mode bit [4] of register MCR is set to one, DDCD reflects changes bit [3] uart_out2 of register MCR. Note: If the DDCD bit is not set and the uart_dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit will get set when the reset is removed if the uart_dcd_n signal remains asserted. **Value** **Description** 0x0 no change on uart_dcd_n since last read of MSR 0x1 change on uart_dcd_n since last read of MSR	RO	0x0

Bit	Name	Description	Access	Reset
2	`teri`	This is used to indicate that a change on the input uart_ri_n (from an active low, to an inactive high state) has occurred since the last time the MSR was read. Reading the MSR clears the TERI bit. In Loopback Mode bit [4] of register MCR is set to one, TERI reflects when bit [2] of register MCR has changed state from a high to a low. **Value** — **Description** 0x0 — no change on uart_ri_n since last read of MSR 0x1 — change on uart_ri_n since last read of MSR	RO	0x0
1	`ddsr`	This is used to indicate that the modem control line uart_dsr_n has changed since the last time the MSR was read. Reading the MSR clears the DDSR bit.In Loopback Mode (MCR[4] set to one), DDSR reflects changes on bit [0] DTR of register MCR . Note, if the DDSR bit is not set and the uart_dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit will get set when the reset is removed if the uart_dsr_n signal remains asserted. **Value** — **Description** 0x0 — no change on uart_dsr_n since last read of MSR 0x1 — change on uart_dsr_n since last read of MSR	RO	0x0
0	`dcts`	This is used to indicate that the modem control line uart_cts_n has changed since the last time the MSR was read. That is: Reading the MSR clears the DCTS bit. In Loopback Mode bit [4] of MCR set to one, DCTS reflects changes on bit [1] RTS of register MCR. Note: If the DCTS bit is not set and the uart_cts_n signal is asserted (low) and a reset occurs (software or otherwise), then the DCTS bit will get set when the reset is removed if the uart_cts_n signal remains asserted. **Value** — **Description** 0x0 — no change on uart_cts_n since last read of MSR 0x1 — change on uart_cts_n since last read of MSR	RO	0x0

srbr Fields

Bit	Name	Description	Access	Reset
7:0	srbr	This is a shadow register for the RBR and has been allocated one 32-bit location so as to accommodate burst accesses from the master.This register contains the data byte received on the serial input port (sin). The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If FIFOs are disabled, bit [0] of register FCR set to zero, the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an overrun error. If FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost. An overrun error will also occur.	RW	0x0

sthr

sthr Fields

Bit	Name	Description	Access	Reset
7:0	`sthr`	This is a shadow register for the THR and has been allocated sixteen 32-bit locations so as to accommodate burst accesses from the master. This register contains data to be transmitted on the serial output port (sout). Data should only be written to the THR when the THR Empty (THRE) bit (LSR[5]) is set. If FIFO's are disabled bit [0] of register FCR set to zero and THRE is set, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If FIFO's are enabled bit [0] of register FCR set to one and THRE is set, 128 characters of data may be written to the THR before the FIFO is full. The UART FIFO depth is configured for 128 characters. Any attempt to write data when the FIFO is full results in the write data being lost.	`RW`	`0x0`

far

This register is used in FIFO access testing.

srt Fields

Bit	Name	Description	Access	Reset
1:0	srt	This can be used to remove the burden of having to store the previously written value to the FCR in memory and having to mask this value so that only the Rx trigger bit gets updated. This is used to select the trigger level in the receiver FIFO at which the Received Data Available Interrupt will be generated. It also determines when the uart_dma_rx_req_n signal will be asserted when DMA Mode (FCR[3]) is set to one. The enum below shows trigger levels that are supported. **Value** / **Description** 0x0 one character in fifo 0x1 FIFO 1/4 full 0x2 FIFO 1/2 full 0x3 FIFO 2 less than full	RW	0x0

stet

This is a shadow register for the Tx empty trigger bits (FCR[5:4]).

Module Instance	Base Address	Register Address
uart0	0xFFC02000	0xFFC020A0
uart1	0xFFC03000	0xFFC030A0

Offset: 0xA0

Access: RW

cpr Fields

Bit	Name	Description	Access	Reset
23:16	fifo_mode	Receiver and Transmitter FIFO depth in bytes. **Value** **Description** 0x80 FIFO Depth 128 bytes	RO	0x37
13	dma_extra	Configures the peripheral to have four additional DMA signals on the interface. **Value** **Description** 0x1 DMA Extra Supported	RO	0x1
12	uart_add_encoded_param	Configures the peripheral to have a configuration identification register. **Value** **Description** 0x1 ID register present	RO	0x1

Bit	Name	Description	Access	Reset
11	shadow	Configures the peripheral to have seven additional registers that shadow some of the existing register bits that are regularly modified by software. These can be used to reduce the software overhead that is introduced by having to perform read-modify writes. **Value** **Description** 0x1 Shadow Supported	RO	0x1
10	fifo_stat	Configures the peripheral to have three additional FIFO status registers. **Value** **Description** 0x1 FIFO Stat Supported	RO	0x1
9	fifo_access	Configures the peripheral to have a programmable FIFO access mode. This is used for test purposes, to allow the receiver FIFO to be written and the transmit FIFO to be read when FIFOs are implemented and enabled. **Value** **Description** 0x1 FIFO Access Supported	RO	0x1
8	additional_feat	Configures the uart to include fifo status register, shadow registers and encoded parameter register. **Value** **Description** 0x1 Additional Features Supported	RO	0x1
7	sir_lp_mode	LP Sir Mode not used in this application. **Value** **Description** 0x0 LP Sir Mode Not Supported	RO	0x0
6	sir_mode	Sir mode not used in this application. **Value** **Description** 0x0 Sir Mode Not Supported	RO	0x0

Bit	Name	Description	Access	Reset
5	`thre_mode`	Programmable Transmitter Hold Register Empty interrupt **Value** **Description** 0x1 Programmable Tx Hold Reg. Empty interrupt present	RO	0x1
4	`afce_mode`	Allows auto flow control. **Value** **Description** 0x1 Auto Flow	RO	0x1
1:0	`apbdatawidth`	Fixed to support an ABP data bus width of 32-bits. **Value** **Description** 0x2 APB Data Width = 32-bits	RO	0x2

ucv

Used only with Additional Features

Module Instance	Base Address	Register Address

Date	Version	Changes
June 2014	2014.06.30	• UART(RS232) Serial Protocol topic added • Interrupts section updated • Updated Interrupt type table • Added address map and register descriptions
February 2014	2014.02.28	Maintenance release
December 2013	2013.12.30	Minor formatting updates.
November 2012	1.2	Minor updates.
May 2012	1.1	Added programming model, address map and register definitions, and reset sections.

Date	Version	Changes
January 2012	1.0	Initial release.

General-Purpose I/O Interface 22

2014.06.30

cv_54022 Subscribe Send Feedback

The hard processor system (HPS) provides three general-purpose I/O (GPIO) interface modules. The GPIO modules are instances of the Synopsys® DesignWare® APB General Purpose Programming I/O (DW_apb_gpio) peripheral.† [45]

Features of the GPIO Interface

The GPIO interface offers the following features:

- Supports digital de-bounce
- Configurable interrupt mode
- Supports up to 67 I/O pins and 14 input-only pins

GPIO Interface Block Diagram and System Integration

The figure below shows a block diagram of the GPIO interface. The following table shows a pin table of the GPIO interface

Functional Description of the GPIO Interface

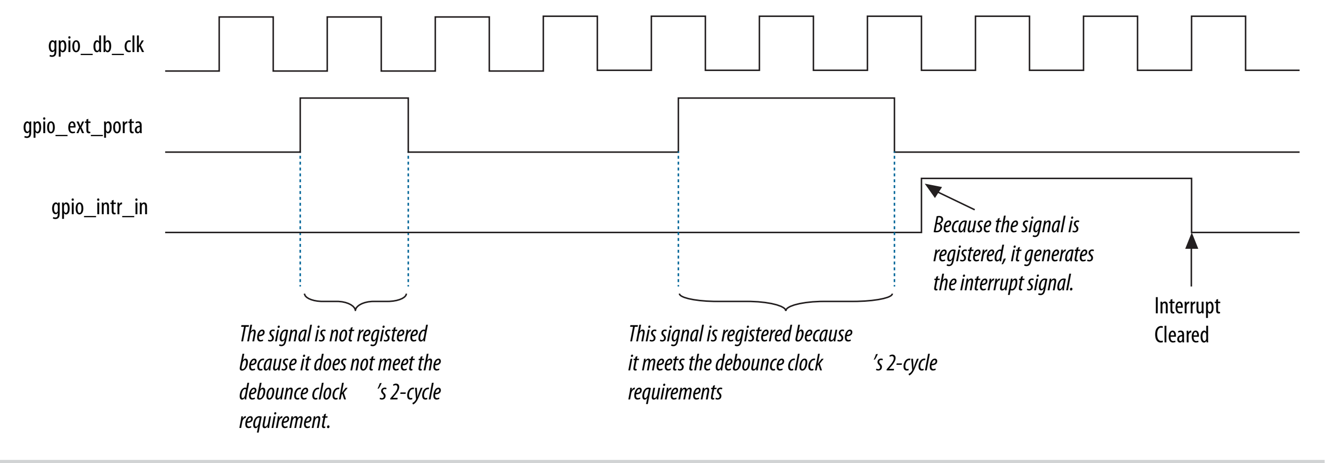
Debounce Operation

The GPIO modules provided in the HPS include optional debounce capabilities. The external signal can be debounced to remove any spurious glitches that are less than one period of the external debouncing clock, `gpio_db_clk`. †

When input signals are debounced using the `gpio_db_clk` debounce clock, the signals must be active for a minimum of two cycles of the debounce clock to guarantee that they are registered. Any input pulse widths less than a debounce clock period are filtered out. If the input signal pulse width is between one and two debounce clock widths it may or may not be filtered out, depending on its phase relationship to the debounce clock. If the input pulse spans two rising edges of the debounce clock, it is registered. If it spans only one rising edge, it is not registered. †

The figure below shows a timing diagram of the debounce circuitry for both cases: a bounced input signal, and later, a propagated input signal.

Figure 22-2: Debounce Timing With Asychronous Reset Flip-Flops



gpio_db_clk
gpio_ext_porta
gpio_intr_in
Because the signal is registered, it generates the interrupt signal.
Interrupt Cleared
The signal is not registered because it does not meet the debounce clock 's 2-cycle requirement.
This signal is registered because it meets the debounce clock 's 2-cycle requirements

Note: Enabling the debounce circuitry increases interrupt latency by two clock cycles of the debounce clock.

Pin Directions

The pins `GPIO0` through `GPIO66` can be configured to be either input or output signals. The pins `HLGPI0` through `HLGPI13` share pins with the HPS DDR controller and are input-only signals.

GPIO Interface Programming Model

Debounce capability for each of the input signals can be enabled or disabled under software control by setting the corresponding bits in the `gpio_debounce` register, accordingly. The debounce clock must be stable and operational before the debounce capability is enabled.

Under software control, the direction of the external I/O pad is controlled by a write to the `gpio_swportx_ddr` register. When configured as input mode, reading `gpio_ext_porta` would read the values on the signal of the external I/O pad. When configured as output mode, the data written to the `gpio_swporta_dr` register drives the output buffer of the I/O pad. The same pins are shared for both input and output modes, so they cannot be configured as input and output modes at the same time. †

GPIO Interface Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

- GPIO Module 0
- GPIO Module 1
- GPIO Module 2

Timer 23

2014.06.30

cv_54023 Subscribe Send Feedback

The hard processor system (HPS) provides four 32-bit general-purpose timers connected to the level 4 (L4) peripheral bus.The timers optionally generate an interrupt when the 32-bit binary count-down timer reaches zero. The timers are instances of the Synopsys® DesignWare® APB Timers (DW_apb_timers) peripheral.†[46]

Related Information

Cortex-A9 MPCore on page 9-4
The MPU subsystem provides additional timers. For more information about the timers in the MPU, refer to the *Cortex-A9 Microprocessor Unit Subsystem* chapter.

Features of the Timer

- Supports interrupt generation
- Supports free-running mode
- Supports user-defined count mode

Timer Block Diagram and System Integration

Each timer includes a slave interface for control and status register (CSR) access, a register block, and a programmable 32-bit down counter that generates interrupts on reaching zero. The timer operates on a single clock domain driven by the clock manager.

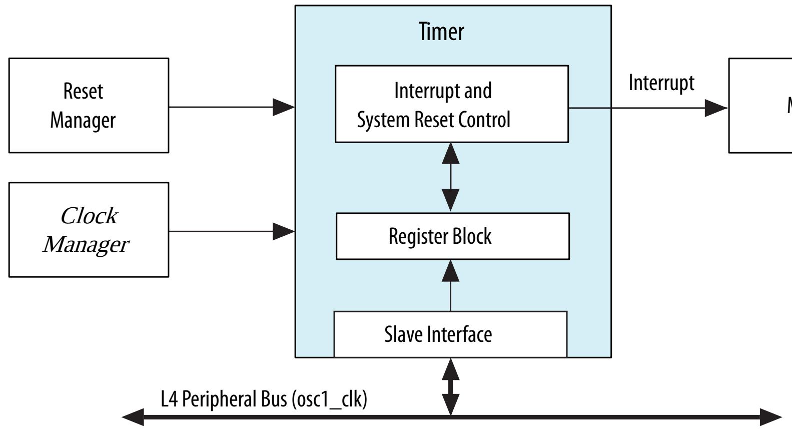
Figure 23-1: Timer Block Diagram



Functional Description of the Timer

The 32-bit timer counts down from a programmed value and generates an interrupt when the count reaches zero. The timer has an independent clock input connected to the system clock signal or to an external clock source. †

The timer supports the following modes of operation:

- Free-running mode—decrementing from the maximum value (0xFFFFFFFF). Reloads maximum value upon reaching zero.
- User-defined count mode—generates a periodic interrupt. Decrements from the user-defined count value loaded from the timer1 load count register (`timer1loadcount`). Reloads the user-defined count upon reaching zero.

The initial value for the timer (that is, the value from which it counts down) is loaded into the timer by the `timer1loadcount` register. The following events can cause a timer to load the initial count from the `timer1loadcount` register: †

- Timer is enabled after being reset or disabled
- Timer counts down to 0

Clocks

Table 23-1: Timer Clock Characteristics

Timer	System Clock	Notes
OSC1 timer 0	`osc1_clk`	—
OSC1 timer 1		
SP timer 0	`l4_sp_clk`	Timer must be disabled if clock frequency changes
SP timer 1		

The timers above are labeled according to the clock it receives. OSC timers receive the oscillator clock `osc1_clk` and the SP timers receives the l4 slave peripheral clock `l4_sp_clk` .

SP timer 0 and SP timer 1 must be disabled before `l4_sp_clk` is changed to another frequency. You can then re-enable the timer once the clock frequency change takes effect. You cannot change the frequency of OSC1 timer 0 and OSC1 timer 1.

Related Information

Clock Manager on page 2-1
For more information about clock performance, refer to the *Clock Manager* chapter.

Resets

The timers are reset by a cold or warm reset. Resetting the timers produces the following results in the following order:

1. The timer is disabled.
2. The interrupt is enabled.
3. The timer enters free-running mode.
4. The timer count load register value is set to zero.

Interrupts

The timer1 interrupt status (`timer1intstat`) and timer1 end of interrupt (`timer1eoi`) registers handle the interrupts. The `timer1intstat` register allows you to read the status of the interrupt. Reading from the `timer1eoi` register clears the interrupt. †

The timer1 control register (`timer1controlreg`) contains the timer1 interrupt mask bit (`timer1_interrupt_mask`) to mask the interrupt. In both the free-running and user-defined count modes of operation, the timer generates an interrupt signal when the timer count reaches zero and the interrupt mask bit of the control register is high.

If the timer interrupt is set, then it is cleared when the timer is disabled.

FPGA Interface

The timer interrupts can be routed to the FPGA interface. You can configure and route the interrupts when you instantiate the HPS component in Qsys.

Related Information

Interrupts on page 27-6
For more information about configuring and routing timer interrupts, refer to the interrupt section of the*Instantiating the HPS Component* chapter in the *Hard Processor System Technical Reference Manual.*

Timer Programming Model

Initialization

To initialize the timer, perform the following steps: †

1. Initialize the timer through the `timer1controlreg` register: †
    - Disable the timer by writing a 0 to the timer1 enable bit (`timer1_enable`) of the `timer1controlreg` register. †

Note: Before writing to a timer1 load count register (`timer1loadcount`), you must disable the timer by writing a 0 to the `timer1_enable` bit of the `timer1controlreg` register to avoid potential synchronization problems. †

- Program the timer mode—user-defined count or free-running—by writing a 0 or 1, respectively, to the timer1 mode bit (`timer1_mode`) of the `timer1controlreg` register. †
- Set the interrupt mask as either masked or not masked by writing a 1 or 0, respectively, to the `timer1_interrupt_mask` bit of the `timer1controlreg` register. †

2. Load the timer counter value into the `timer1loadcount` register. †
3. Enable the timer by writing a 1 to the `timer1_enable` bit of the `timer1controlreg` register. †

Enabling the Timer

When a timer transitions to the enabled state, the current value of `timer1loadcount` register is loaded into the timer counter. †

1. To enable the timer, write a 1 to the `timer1_enable` bit of the `timer1controlreg` register.

Disabling the Timer

When the timer enable bit is cleared to 0, the timer counter and any associated registers in the timer clock domain, are asynchronously reset. †

1. To disable the timer, write a 0 to the `timer1_enable` bit. †

Loading the Timer Countdown Value

When a timer counter is enabled after being reset or disabled, the count value is loaded from the `timer1loadcount` register; this occurs in both free-running and user-defined count modes. †

When a timer counts down to 0, it loads one of two values, depending on the timer operating mode: †

- User-defined count mode—timer loads the current value of the `timer1loadcount` register. Use this mode if you want a fixed, timed interrupt. Designate this mode by writing a 1 to the `timer1_mode` bit of the `timer1controlreg` register. †
- Free-running mode—timer loads the maximum value (0xFFFFFFFF). The timer max count value allows for a maximum amount of time to reprogram or disable the timer before another interrupt occurs. Use this mode if you want a single timed interrupt. Enable this mode by writing a 0 to the `timer1_mode` bit of the `timer1controlreg` register. †

Servicing Interrupts

Clearing the Interrupt

An active timer interrupt can be cleared in two ways.

1. If you clear the interrupt at the same time as the timer reaches 0, the interrupt remains asserted. This action happens because setting the timer interrupt takes precedence over clearing the interrupt. †
2. To clear an active timer interrupt, read the `timer1eoi` register or disable the timer. When the timer is enabled, its interrupt remains asserted until it is cleared by reading the `timer1eoi` register. †

Checking the Interrupt Status

You can query the interrupt status of the timer without clearing its interrupt.

1. To check the interrupt status, read the `timer1intstat` register. †

Masking the Interrupt

The timer interrupt can be masked using the `timer1controlreg` register.

To mask an interrupt, write a 1 to the `timer1_interrupt_mask` bit of the `timer1controlreg` register. †

Timer Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

- OSC1 Timer Module 0
- OSC1 Timer Module 1
- SP Timer Module 0
- SP Timer Module 1

Watchdog Timer 24

2014.06.30

cv_54024 Subscribe Send Feedback

The watchdog timers are peripherals you can use to recover from system lockup that might be caused by software or system related issues. The hard processor system (HPS) provides two programmable watchdog timers, which are connected to the level 4 (L4) peripheral bus. The watchdog timers are instances of the Synopsys® DesignWare® APB Watchdog Timer (DW_apb_wdt) peripheral. [47]

The microprocessor unit (MPU) subsystem provides two additional watchdog timers.

Related Information

Cortex-A9 MPCore on page 9-4
For more information about the watchdog timers in the MPU, refer to *Cortex A9 Microprocessor Unit Subsystem* chapter.

Features of the Watchdog Timer

The following list describes the features of the watchdog timer:

- Programmable 32-bit timeout range
- Timer counts down from a preset value to zero, then performs one of the following user-configurable operations:
  - Generates a system reset †
  - Generates an interrupt, restarts the timer, and if the timer is not cleared before a second timeout occurs, generates a system reset
- Dual programmable timeout period, used when the time to wait after the first start is different than that required for subsequent restarts †
- Prevention of accidental restart of the watchdog counter †
- Prevention of accidental disabling of the watchdog counter †
- Pause mode for debugging

Watchdog Timer Block Diagram and System Integration

Each watchdog timer consists of a slave interface for control and status register (CSR) access, a register block, and a 32-bit down counter that operates on the slave interface clock (`osc1_clk`). A pause input, driven by the system manager, optionally pauses the counter when a CPU is being debugged.

The watchdog timer drives an interrupt request to the MPU and a reset request to the reset manager.

Figure 24-1: Watchdog Timer Block Diagram

Functional Description of the Watchdog Timer

Watchdog Timer Counter

Each watchdog timer is a programmable, little-endian down counter that decrements by one on each clock cycle. The watchdog timer supports 16 fixed timeout period values, Software chooses which timeout periods are desired. A timeout period is 2<*n*> `osc1_clk` clock periods, where *n* is an integer from 16 to 31 inclusive.

Software must regularly restart the timer (which reloads the counter with the restart timeout period value) to indicate that the system is functioning normally. Software can reload the counter at any time by writing to the restart register. If the counter reaches zero, the watchdog timer has timed out, indicating an unrecoverable error has occurred and a system reset is needed.

Software configures the watchdog timer to one of the following output response modes:

- On timeout, generate a reset request.
- On timeout, assert an interrupt request and restart the watchdog timer. Software must service the interrupt and reset the watchdog timer before a second timeout occurs. Otherwise, generate a reset request.

If a restart occurs at the same time the watchdog counter reaches zero, an interrupt is not generated.

Related Information

- **Watchdog Timer Clocks** on page 24-3
- **Setting the Timeout Period Values** on page 24-4
- **Selecting the Output Response Mode** on page 24-4
- **Reloading a Watchdog Counter** on page 24-5

Watchdog Timer Pause Mode

The watchdog timers can be paused during debugging. The watchdog timer pause mode is controlled by the system manager. The following options are available:

- Pause the timer while either CPU0 or CPU1 is in debug mode
- Pause the timer while only CPU1 is in debug mode
- Pause the timer while only CPU0 is in debug mode
- Do not pause the timer

When pause mode is enabled, the system manager pauses the watchdog timer while debugging. When pause mode is disabled, the watchdog timer runs while debugging.

At reset, the watchdog pausing feature is enabled for both CPUs by default.

Related Information

Pausing a Watchdog Timer on page 24-5

Watchdog Timer Clocks

Each watchdog timer is connected to the `osc1_clk` clock so that timer operation is not dependent on the phase-locked loops (PLLs) in the clock manager. This independence allows recovery from software that inadvertently programs the PLLs in the clock manager incorrectly.

Related Information

Clock Manager on page 2-1
For more information, refer to the *Clock Manager* chapter.

Watchdog Timer Resets

Watchdog timers are reset by a cold or warm reset from the reset manager, and are disabled when exiting reset. †

Related Information

Reset Manager on page 3-1
For more information, refer to the *Reset Manager* chapter.

FPGA Interface

The watchdog timer interrupts can be routed to the FPGA interface. You can configure and route the interrupts when you instantiate the HPS component in Qsys

Related Information

Interrupts on page 27-6
For more information, refer to the *Instantiating the HPS Component* chapter in the *Hard Processor System Technical Reference Manual.*

Watchdog Timer Programming Model

Setting the Timeout Period Values

The watchdog timers have a dual timeout period. The counter uses the initial start timeout period value the first the timer is started. All subsequent restarts use the restart timeout period. The valid values are $2^{(16+<i>)}$ – 1 clock cycles, where i is an integer from 0 to 15. To set the programmable timeout periods, perform the following actions in no specific order:

Note: Set the timeout values before enabling the timer.

- To set the initial start timeout period, write i to the timeout period for the initialization field (`top_init`) of the watchdog timeout range register (`wdt_torr`).
- To set the restart timeout period, write i to the timeout period field (`top`) of the `wdt_torr` register

Selecting the Output Response Mode

The watchdog timers have two output response modes. To select the desired mode, perform one of the following actions:

- To generate a system reset request when a timeout occurs, write 0 to the output response mode bit (`rmod`) of the watchdog timer control register (`wdt_cr`).
- To generate an interrupt and restart the timer when a timeout occurs, write 1 to the `rmod` field of the `wdt_cr` register.

If a restart occurs at the same time the watchdog counter reaches zero, a system reset is not generated. †

Related Information

Watchdog Timer Counter on page 24-3

Enabling and Initially Starting a Watchdog Timer

To enable and start a watchdog timer, write the value 1 to the watchdog timer enable bit (`wdt_en`) of the `wdt_cr` register.

Reloading a Watchdog Counter

To reload a watchdog counter, write the value 0x76 to the counter restart register (`wdt_crr`). This unique 8-bit value is used as a safety feature to prevent accidental restarts.

Pausing a Watchdog Timer

Pausing the watchdog timers is controlled by the L4 watchdog debug register (`wddbg`) in the system manager.

Related Information

Features of the System Manager on page 5-1
For more information, refer to the *System Manager* chapter.

Disabling and Stopping a Watchdog Timer

The watchdog timers are disabled and stopped by resetting them from the reset manager.

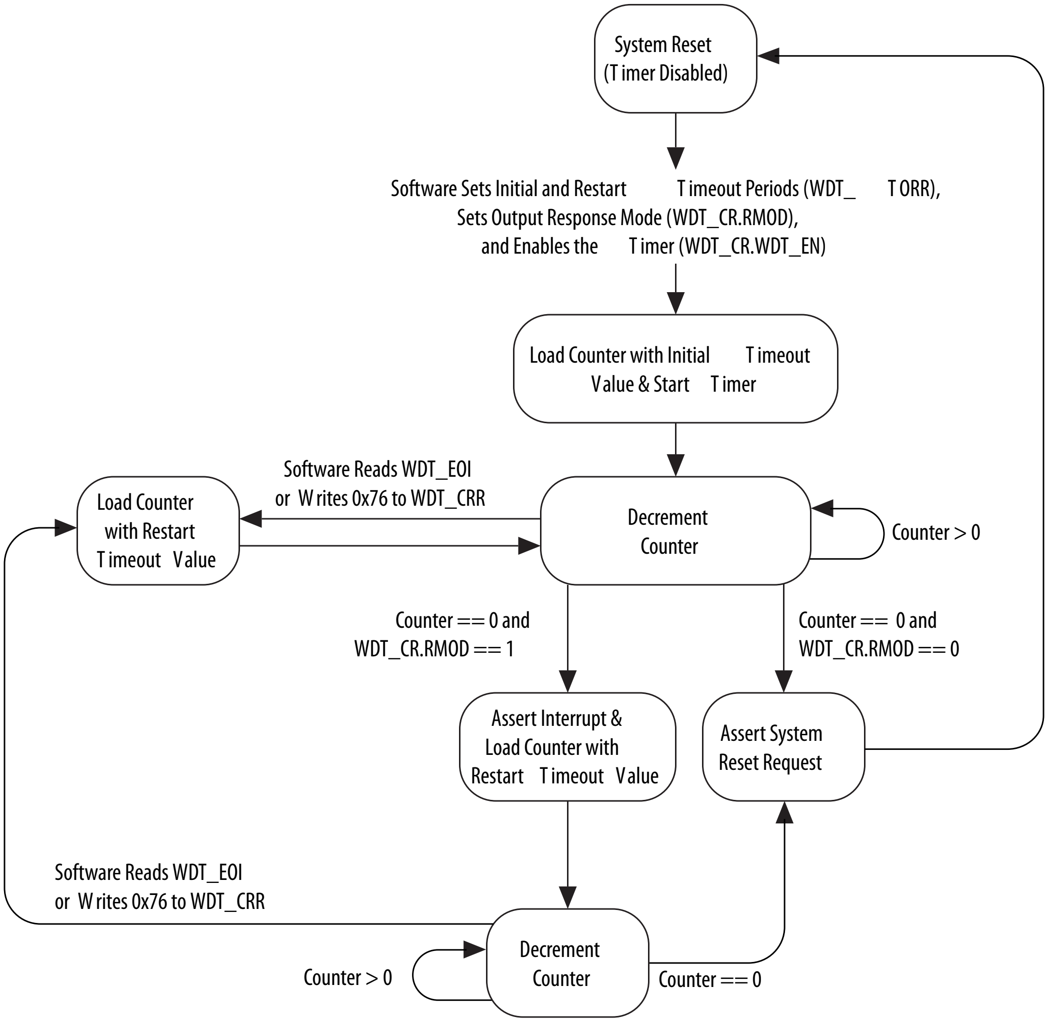
Related Information

Reset Manager on page 3-1
For more information, refer to the *Reset Manager* chapter.

Watchdog Timer State Machine

The following figure illustrates the behavior of the watchdog timer, including the behavior of both output response modes. Once initialized, the counter decrements at every clock cycle. The state machine remains in the Decrement Counter state until the counter reaches zero, or the watchdog timer is restarted. If software reads the interrupt clear register (`wdt_eoi`), or writes 0x76 to the `wdt_crr` register, the state changes from Decrement Counter to Load Counter with Restart Timeout Value. In this state, the watchdog counter gets reloaded with the restart timeout value, and then the state changes back to Decrement Counter.

Figure 24-2: Watchdog Timer State Machine



System Reset (Timer Disabled)
Software Sets Initial and Restart Timeout Periods (WDT_TORR), Sets Output Response Mode (WDT_CR.RMOD), and Enables the Timer (WDT_CR.WDT_EN)
Load Counter with Initial Timeout Value & Start Timer
Software Reads WDT_EOI or Writes 0x76 to WDT_CRR
Load Counter with Restart Timeout Value
Decrement Counter
Counter > 0
Counter == 0 and WDT_CR.RMOD == 1
Counter == 0 and WDT_CR.RMOD == 0
Assert Interrupt & Load Counter with Restart Timeout Value
Assert System Reset Request
Software Reads WDT_EOI or Writes 0x76 to WDT_CRR
Counter > 0
Decrement Counter
Counter == 0

If the counter reaches zero, the state changes based on the value of the output response mode setting defined in the rmod bit of the wdt_cr register. If the rmod bit of the wdt_cr register is 0, the output response mode is to generate a system reset request. In this case, the state changes to Assert System Reset Request. In response, the reset manager resets and disables the watchdog timer, and gives software the opportunity to reinitialize the timer.

If the rmod bit of the wdt_cr register is 1, the output response mode is to generate an interrupt. In this case, the state changes to Assert Interrupt and Load Counter with Restart Timeout Value. An interrupt to the processor is generated, and the watchdog counter is reloaded with the restart timeout value. The state then changes to the second Decrement Counter state, and the counter resumes decrementing. If software reads the wdt_eoi register, or writes 0x76 to the wdt_crr register, the state changes from Decrement Counter to Load Counter with Restart Timeout Value. In this state, the watchdog counter gets reloaded with the restart timeout value, and then the state changes back to the first Decrement Counter state. If the counter again reaches zero, the state changes to Assert System Reset Request. In response, the reset manager resets the watchdog timer, and gives software the opportunity to reinitialize the timer.

Watchdog Timer Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridge consist of the following regions:

- L4 Watchdog Module 0
- L4 Watchdog Module 1

CAN Controller Introduction 25

2014.06.30

cv_54025 Subscribe Send Feedback

The hard processor system (HPS) provides two controller area network (CAN) controllers for serial communication with the Cortex-A9 microprocessor unit (MPU) subsystem host processor and the direct memory access (DMA) controller using the CAN protocol. The CAN controllers are instances of the Bosch D_CAN controller and compliant with ISO 11898-1.

Features of the CAN Controller

The CAN controllers offer the following features:

- Compliant with CAN Protocol Specification 2.0 parts A and B, available from the Bosch website.
- Programmable communication rate up to 1 Mbps
- Holds up to 128 messages
- Error correction code (ECC)
- 11-bit standard and 29-bit extended identifiers
- Programmable loopback mode
- External direct memory access (DMA) controller for large data transfers
- Automatic retransmission

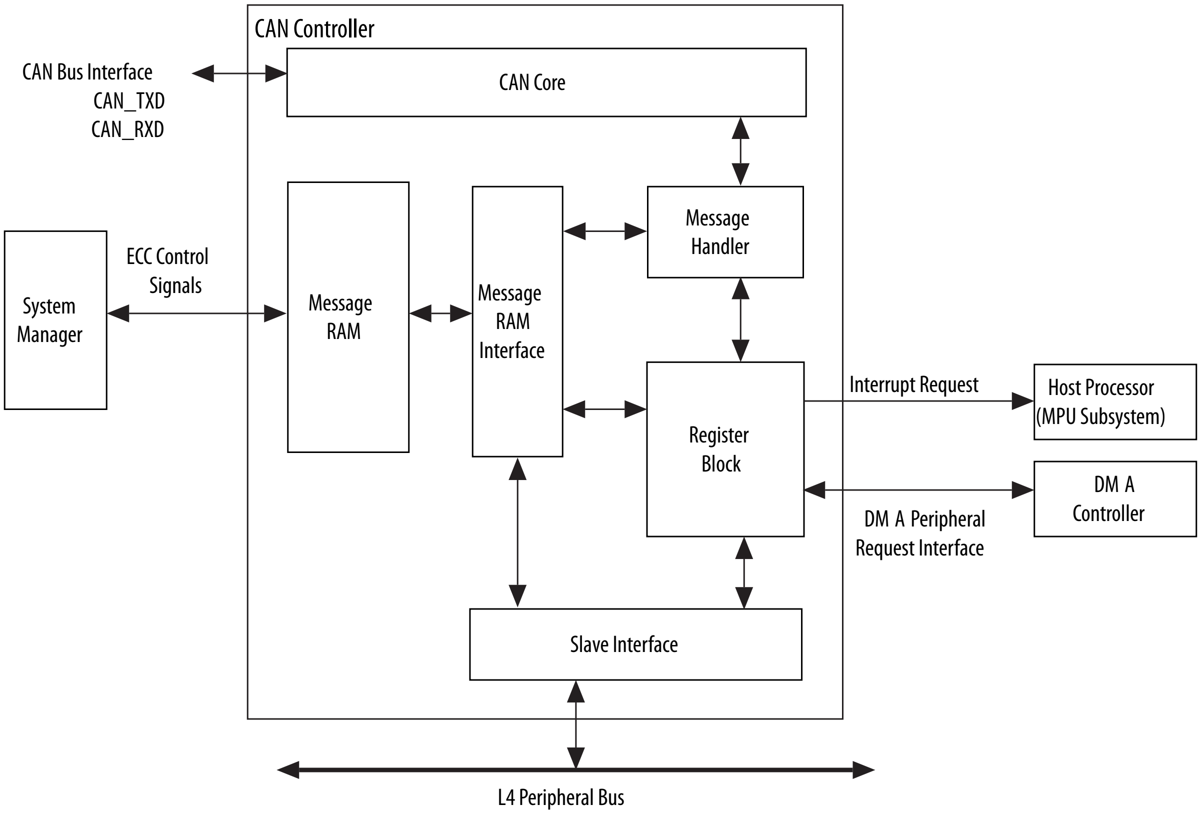
CAN Controller Block Diagram and System Integration

Figure 25-1: CAN Controller Block Diagram



The CAN controller consists of the following modules and interfaces:

- CAN core
  - Connects to the CAN bus interface
  - Handles all ISO 11898-1 protocol functions
- Message handler
  - State machine that controls the data transfer between the message RAM and CAN core.
  - Handles acceptance filtering and the interrupt generation
- Message RAM
  - Storage for up to 128 messages objects
  - Single bit error correction and double bit error detection
- Message RAM interface
  - Two separate interfaces, `IF1` and `IF2`
- Register block
  - Control and status registers (CSR) for module setup and indirect message object access.
  - All host processor accesses to the message RAM are relayed through the message RAM interface.
- Level 4 (L4) slave interface for CSR accesses

Functional Description of the CAN Controller

The CAN controllers perform communication according to the CAN protocol version 2.0 parts A and B. All communication on the CAN bus is through message objects. The CAN controller stores message objects in its internal message RAM. The host processor cannot access the message RAM directly, instead the `IF1` and `IF2` message interface register sets provide the host processor access to the messages. Messages are passed between the message RAM and the CAN core by the message handler. The message handler is also responsible for message level responsibilities such as acceptance filtering, interrupt generation, and transmission request generation.

Message Object

The message RAM can store up to 128 message objects. To avoid conflicts between host processor accesses to the message RAM and CAN message reception and transmission, the host processor does not access the message objects directly. Accesses are handled through the `IF1` and `IF2` message interface registers.

The following table shows the structure of a message object, where the first row contains the message object control flags, the second row contains the message object masks, and the third row is the CAN message.

Table 25-1: Message Object Structure

MsgVal				NewDat	MsgLst	IntPnd		TxIE	RxIE	RmtEn	TxRqst	EoB
UMask	Msk [28:0]	MXtd	MDir									

	ID [28:0]	Xtd	Dir	DLC [3:0]	Data 0 [7:0]	Data 1 [7:0]	Data 2 [7:0]	Data 3 [7:0]	Data 4 [7:0]	Data 5 [7:0]	Data 6 [7:0]	Data 7 [7:0]

Message Object Control Flags

Message Valid (`MsgVal`)

- 0= The message object is ignored by the message handler
- 1= The message object is configured and should be considered by the message handler

The host processor must set the `MsgVal` bit of all unused message objects to 0 before it resets the initialization bit (`Init`) of the CAN control register (`CCTRL`) to initialize the CAN controller. `MsgVal` must also be set to 0 when the message object is no longer in use.

The `MsgVal` field is directly readable from the message valid registers (`MOVALA`, `MOVALB`, `MOVALC`, `MOVALD`, and `MOVALX`). However, to write to the `MsgVal` field for a specific message object, the host processor must write to the message interface registers.

New Data (`NewDat`)

- 0= No new data has been written into the data portion of this message object by the message handler since last time this flag was cleared by the host processor.
- 1= The message handler or the host processor has written new data to the data portion of this message object.

The `NewDat` field is directly readable from the new data registers (`MONDA`, `MONDB`, `MONDC`, `MONDD`, and `MONDX`). However, to write to the `NewDat` field for a specific message object, the host processor must write to the message interface registers.

Message Lost (`MsgLst`)

- 0= No message lost since last time this bit is was last reset by the host processor
- 1= The message handler stored a new message into this object when the `NewDat` bit was still set, indicating the host processor has lost a message.

`MsgLst` is valid only in message objects with the message direction bit (`Dir`) set to receive.

Interrupt Pending (IntPnd)

- 0= This message object is not the source of an interrupt.
- 1= This message object is the source of an interrupt. The interrupt identifier field in the CAN interrupt register (CIR) points to this message object if there is no other interrupt source with higher priority.

The IntPnd field is directly readable from the interrupt pending registers (MOIPA, MOIPB, MOIPC, MOIPD, and MOIPX). However, to write to the IntPnd field for a specific message object, the host processor must write to the message interface registers.

Transmit Interrupt Enable (TxIE)

- 0= TxIE is disabled. IntPnd is left unchanged after the successful transmission of a frame.
- 1= TxIE is enabled. IntPnd is set after a successful transmission of a frame.

Receive Interrupt Enable (RxIE)

- 0= RxIE is disabled. IntPnd is left unchanged after a successful reception of a frame.
- 1= RxIE is enabled. IntPnd is set after a successful reception of a frame.

Remote Enable (RmtEn)

- 0= RmtEn is disabled. At the reception of a remote frame, TxRqst is left unchanged.
- 1= RmtEn is enabled. At the reception of a remote frame, TxRqst is set.

Transmit Request (TxRqst)

- 0= This message object is not waiting for transmission.
- 1= The transmission of this message object is requested and is not complete.

The TxRqst field is directly readable from the transmission request registers (MOTRA, MOTRB, MOTRC, MOTRD, and MOTRX). However, to write to the TxRqst field for a specific message object, the host processor must write to the message interface registers.

End of Block (EoB)

- 0= Message object belongs to a FIFO buffer block and is not the last message object of that FIFO buffer block.
- 1= Single message object or last message object of a FIFO buffer block.

This bit is used to concatenate two or more message objects (up to 128) to build a FIFO buffer. For single message objects (not belonging to a FIFO buffer), this bit must always be set to 1.

Message Object Mask Bits

The message object mask bits, together with the arbitration bits, are used for acceptance filtering of incoming messages.

Use Acceptance Mask (UMask) on page 25-6

Identifier Mask (Msk[28:0]) on page 25-6

Extended Identifier Mask (MXtd) on page 25-6

Mask Message Direction (MDir) on page 25-6

Use Acceptance Mask (UMask)

- 0= Ignore mask. Msk[28:0], MXtd, and Mdir have no effect on acceptance filtering. For an incoming message to be accepted, all the following conditions must be met:
  - The received message is a data frame with message direction set to 0 (receive) or is a remote frame with message direction set to 1 (transmit).
  - The received message identifier matches the message identifier (ID[28:0]) of the message object.
  - The received identifier extension bit matches the identifier extension bit (Xtd) of the message object.
- 1= Use mask (Msk[28:0], MXtd, and MDir) for acceptance filtering if the respective mask bits are set up for acceptance filtering. For an incoming message to be accepted, all the following conditions must be met:
  - The received message is a data frame with message direction set to 0 (receive) or is a remote frame with message direction set to 1 (transmit) with the MDir mask bit enabled.
  - The received message identifier matches the message identifier (ID[28:0]) of the message object with the Msk[28:0] mask bits enabled
  - The received identifier extension bit matches the identifier extension bit (Xtd) of the message object, with the MXtd mask bit enabled.

Note: If the UMask bit is set to 1, the message object's mask bits have to be programmed during the initialization of the message object before MsgVal is set to 1.

Identifier Mask (Msk[28:0])

The identifier mask filters the corresponding bits in ID[28:0].

- 0= The corresponding identifier bit has no effect on the acceptance filter.
- 1= The corresponding identifier bit is used for acceptance filtering.

Extended Identifier Mask (MXtd)

- 0= The extended frame identifier bit (Xtd) has no effect on the acceptance filtering
- 1= The extended frame identifier bit (Xtd) is used for acceptance filtering

When 11-bit (standard) identifiers are used for a message object, the identifiers of received data frames are written to bits ID28 to ID18. For acceptance filtering, only these bits, together with mask bits Msk28 to Msk18, are used.

Mask Message Direction (MDir)

- 0= The message direction bit (Dir) has no effect on the acceptance filtering.
- 1= The message direction bit (Dir) is used for acceptance filtering.

Important: Altera recommends always setting MDir to 1. Ignoring the message direction bit is an advanced technique that must be handled with great care.

CAN Message Bits

The arbitration fields ID28-0, Xtd, and Dir are used to define the identifier and type of outgoing messages and are used (together with the mask fields Msk28-0, MXtd, and MDir) for acceptance filtering of incoming messages. A received message is stored to the valid message object with matching identifier when the direction is set to receive a data frame or transmit a remote frame. Extended frames can be stored only in message objects with Xtd is set to 1, standard frames in message objects with Xtd is set to 0. If a received message (data frame or remote frame) matches more than one valid message object, it is stored to the object with the lowest message number.

Message Identifier (ID[28:0])

- ID28-ID0: 29-bit identifier (extended frame)
- ID28-ID18: 11-bit identifier (standard frame)

Extended Frame Identifier (Xtd)

- 0= The 11-bit (standard) identifier is used for this message object.
- 1= The 29-bit (extended) identifier is used for this message object.

Message Direction (Dir)

- 0= receive direction. When TxRqst is set to 1, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, that message is stored in this message object.
- 1= transmit direction. When TxRqst is set to 1, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set to 1 (if RmtEn = 1).

Data Length Code (DLC[3:0])

DLC specifies the number of data bytes in the data frame. The maximum number is eight.

The data length code (DLC) of a message object must be defined the same as in all the corresponding objects with the same identifier in all CAN devices. When the message handler stores a data frame, it sets the DLC field to the value provided in the received message.

Data Bytes 0-7 (Data 0[7:0] - Data 7[7:0])

The data bytes in a CAN data frame.

Message Interface Registers

There are two sets of message interface registers, IF1 and IF2, that provide a means for a host processor or DMA controller to access any message object indirectly. Message objects are transferred between the message RAM and the message buffer registers as a single, atomic operation maintaining data consistency across the message.

Table 25-2: Message Interface Register Set

This table lists the structure of each message interface register set, where *x* represents either set 1 or set 2.

Register Type	Register	Name	Description
Command	IFxCMR	IFx command register	Specifies the transfer direction and selects the portions of the message object to transfer

Register Type	Register	Name	Description
Message buffer	IFxMSK	IFx mask register	Provides access to the Msk, MDir, and MXtd mask fields of the message object
	IFxARB	IFx arbitration register	Provides access to the ID, Dir, Xtd, and MsgVal arbitration fields of the message object
	IFxMCTR	IFx message control register	Provides access to the DLC, EoB, TxRqst, RmtEn, RxIE, TxIE, UMask, IntPnd, MsgLst, and NewDat fields of the message object
	IFxDA	IFx data A register	Provides access to data bytes 0-3 of the message object
	IFxDB	IFx data B register	Provides access to data bytes 4-7 of the message object

DMA Mode

The CAN controller can issue DMA controller requests to transfer data between one or both of the message interface registers and system memory. The CAN controller has two DMA request interfaces, called can_if1dma and can_if2dma. The CAN peripheral request interfaces are shared with the FPGA DMA peripheral request interfaces. To use the DMA peripheral request interface, the host processor must access the CAN control register (CCTRL) in the protocol group (protogrp). The peripheral request interface is selected through the system manager.

To activate the DMA support feature and initiate a transfer, write a 1 to the DMAactive bit in the appropriate IF command register (IFxCMR) in the message interface group (msgifgrp). After the message object transfer is completed, the CAN controller issues a DMA peripheral request to perform the next message object transfer. The request remains active until the first read or write to the message interface register.

Related Information

- **DMA Controller** on page 16-1
- **Features of the System Manager** on page 5-1

Automatic Retransmission

The CAN controller provides a means for automatic retransmission of frames that have lost arbitration or have errors during transmission. Retransmission happens automatically without user intervention or notification. Normal confirmation is given when the transmission is successfully complete.

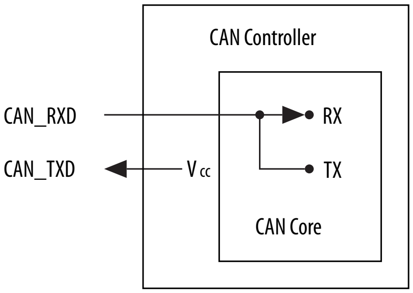
Test Mode

To enable test mode, set the test mode enable bit (Test) in the CCTRL register to 1. This action activates write access to the CAN test register (CTR).

Silent Mode

The CAN controller is set in the silent mode by programming the silent mode (`Silent`) bit in the test register (`CTR`) to 1. In silent mode, the CAN controller is able to receive valid data frames and valid remote frames, but it holds the `CAN_TXD` pin high, sending no data to the CAN bus. The silent mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (acknowledge bits, error frames). In ISO 11898-1, the silent mode is called the *bus monitoring mode*.

Figure 25-2: CAN Core in Silent Mode

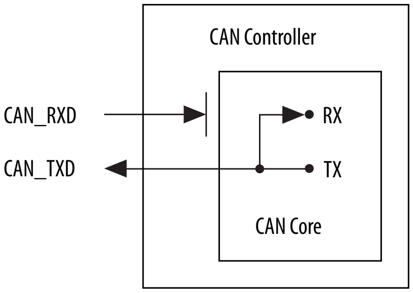


Loopback Mode

The CAN controller is set in loopback mode by programming the loopback mode (`LBack`) bit in the test register (`CTR`) to 1. In loopback mode, the CAN controller treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) to a receive buffer.

To be independent from external stimulation, the CAN controller ignores acknowledge errors in loopback mode. In this mode, the CAN controller provides internal feedback from its transmit (TX) output to its receive (RX) input. The actual value of the input pin is disregarded by the CAN controller.

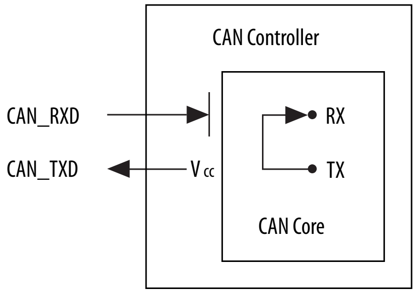
Figure 25-3: CAN Core in Loopback Mode



Combined Mode

The CAN controller is set in combined loopback and silent mode by programming the silent mode (`Silent`) and loopback mode (`LBack`) bits in the test register (`CTR`) to 1. Combined mode can be used for testing the CAN hardware without affecting other devices connected to the CAN bus. In this mode, the `CAN_RXD` pin is disconnected from the CAN core and the `CAN_TXD` pin is held high.

Figure 25-4: CAN Core in Combined Mode



L4 Slave Interface

The host processor accesses data, control, and status information of the CAN controller through the L4 slave interface. The slave interface supports 32-bit accesses only.

Note: This interface does not support error responses.

Clocks

The CAN controller operates on the `l4_sp_clk` and `can_clk` clock inputs. The `l4_sp_clk` clock is used by the L4 slave interface and the `can_clk` is used to operate the CAN core.

The `can_clk` clock must be programmed to be at least eight times the CAN bus interface speed. For example, for a CAN bus interface operating at a 1 Mbps baud rate, the `can_clk` clock must be set to at least 8 MHz. The `l4_sp_clk` clock can operate at a clock frequency that is equal to or greater than the `can_clk` frequency.

Related Information

Clock Manager on page 2-1
For more information about the `l4_sp_clk` and `can_clk` clocks, refer to the *Clock Manager* chapter.

Software Reset

Software initialization is done by setting the `Init` bit in the CAN control register (`CCTRL`) in the protocol group (`protogrp`) in the CAN controller register map. This bit is set through the CAN protocol when a bus off condition occurs on the CAN link. The bit is also set through the hardware reset input described in Hardware Reset.

Due to the synchronization mechanism between the two clock domains, there might be a delay until the value written to the `Init` bit can be read back. To assure that the previous value written has been accepted, read the `Init` bit before setting it to a new value.

The bus off recovery sequence cannot be shortened by setting or resetting the `Init` bit. For more information about bus off, refer to the CAN Protocol Specification 2.0 parts A and B, available from the Bosch website.

Related Information

- **Hardware Reset** on page 25-11
- **http://www.bosch-semiconductors.de/en/ubk_semiconductors/homepage/homepage_1.html**

Hardware Reset

Each CAN controller has a separate reset signal. The reset manager drives the signals on a cold or warm reset. The reset signal is synchronized to both clock domains and applied to the appropriate logic within the CAN controllers.

Related Information

Reset Manager on page 3-1
For more information, refer to the *Reset Manager* chapter.

Interrupts

Each CAN controller generates two interrupt signals. One signal indicates error and status interrupts and the other signal indicates message object interrupts. Both interrupt signals connect to the global interrupt controller (GIC). Interrupts are enabled in the CAN control register (`CCTRL`) in the protocol group (`protogrp`). The CAN interrupt register (`CIR`) in the protocol group (`protogrp`) indicates the highest priority interrupt that is pending.

Error Interrupts

The following error conditions generate interrupts:

- Bus off—when the transmit error count is equal to or greater than 256, the bus off (`BOff`) bit in the CAN status register (`CSTS`) in the protocol group (`protogrp`) is set to 1.
- Error warning—when either the transmit error counter or the receive error counters reaches 96, the error warning status (`EWarn`) bit in the CAN status register (`CSTS`) in the protocol group (`protogrp`) is set to 1.

Status Interrupts

The following status conditions generate interrupts:

- Receive OK—when the CAN controller receives a message successfully, the `RxOK` bit in the CAN status register (`CSTS`) in the protocol group (`protogrp`) is set to 1.
- Transmit OK—when the CAN controller transmits a message successfully, the `TxOK` bit in the CAN status register (`CSTS`) in the protocol group (`protogrp`) is set to 1.
- Last error code—when a message is received or transmitted with an error, the `LEC` bits in the CAN status register (`CSTS`) in the protocol group (`protogrp`) are set according to the error type.

Message Object Interrupts

The `IntPnd` bits from the message objects can generate interrupts when the corresponding message object `TxIE` bit or `RxIE` bit is set to 1. The table lists the location of message object interrupt information in the interrupt pending registers. The interrupt pending registers are located in the message handler group (`msghandgrp`).

Table 25-3: Message Object Interrupt Registers

Register	Title	Message Objects
`MOIPA`	Interrupt pending A register	1 to 32

Register	Title	Message Objects
MOIPB	Interrupt pending B register	33 to 64
MOIPC	Interrupt pending C register	65 to 96
MOIPD	Interrupt pending D register	97 to 128

The MOIPX register allows software to quickly detect which message object group has a pending interrupt.

CAN Controller Programming Model

Software Initialization

The software initialization is started by setting the Init bit in the CAN control register (CCTRL) to 1. While the Init bit is 1, messages are not transferred to or from the CAN bus, and the CAN_TXD CAN bus output is held in the high state. Setting the Init bit does not change any configuration registers.

To initialize the CAN controller, the host processor must program the CAN bit timing (CBT) register and message objects that will be used for CAN communication. If a message object is not needed, it is sufficient to set the MsgVal bit of the message object to not valid (0), which is the default after RAM initialization. You must set up the entire message object before setting MsgVal bit to valid (1). The message objects are set up through either message interface register set.

Access to the CAN bit timing (CBT) register is only enabled when the configuration change enable (CCE) and Init bits in the CAN control register (CCTRL) are both set to 1.

Setting the Init bit to 0 finishes the software initialization. The CAN core synchronizes itself to the data transfer on the CAN bus by waiting for the bus to reach an idle state before it can take part in bus activities and message transfers.

The initialization of the message objects is independent of the CAN controller initialization and can be done anytime, but the message objects should all be configured to particular identifiers or set to not valid before message transferring begins.

On power up, the message RAM has to be initialized. To initialize RAM, set the Init bit to 1, then set the RAMInit bit in the CAN function register (CFR) in the protocol group (protogrp) to 1. The RAMInit bit returns to 0 when RAM initialization completes. During RAM initialization, all message objects are cleared to zero and the RAM ECC bits are initialized. Access to RAM is not allowed prior to or during RAM initialization.

CAN Message Transfer

Once the CAN controller is initialized, the CAN controller synchronizes itself to the CAN bus and starts transferring messages.

Received messages are stored to their appropriate message objects, if they pass the message handler's acceptance filtering. The entire message, including all arbitration bits, Xtd, Dir, DLC, eight data bytes, the mask and control bits UMask, MXtd, MDir, EoB, MsgLst, RxIE, TxIE, and RmtEn, is stored in the message object. Masked arbitration bits might change in the message object when a received message is stored.

The host processor may read or update each message at any time using the message interface registers. The message handler guarantees data consistency when the host processor accesses the message object at the same time the message is being transferred to or from RAM.

Messages to be transmitted are updated by the host processor. If a permanent message object (arbitration and control bits set up during configuration are unchanged for multiple CAN transfers) exists for the message, only the data bytes need to be updated. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time they are transmitted, according to their internal priority. The message object numbers are 1 to 128, with 1 being the lowest internal priority and 128 the highest priority. Messages may be updated or set to invalid (`MsgVal`=0) at anytime, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started.

Depending on the configuration on the message object, the transmission of a message may be requested automatically by the reception of a remote frame with a matching identifier. Remote frames are frames used to request a particular message on the CAN network.

Note: For ease in programming, Altera recommends using one `IF` message interface for all receive direction activity and the other `IF` message interface for all transmit direction activity.

Message Object Reconfiguration for Frame Reception

To configure a message object to receive data frames, set the `Dir` field to 0.

To configure a message object to receive remote frames, set the `Dir` field to 1, set `UMask` to 1, and set `RmtEn` to 0.

To avoid modifying an object while it is being transmitted, you must set `MsgVal` to 0 before changing any of the following configuration and control bits:

- `ID[28:0]`
- `Xtd`
- `DLC[3:0]`
- `RxIE`
- `TxIE`
- `RmtEn`
- `EoB`
- `UMask`
- `Msk[28:0]`
- `MXtd`
- `MDir`

The following fields of a message object can be changed without clearing `MsgVal`:

- `Data0[7:0] to Data7[7:0]`
- `TxRqst`
- `NewDat`
- `MsgLst`
- `IntPnd`

Message Object Reconfiguration for Frame Transmission

To configure a message object to transmit data frames, set the `Dir` field to 1, and either set `UMask` to 0 or set `RmtEn` to 1.

Before changing any of the following configuration and control bits, you must set `MsgVal` to 0:

- `Dir`
- `RxIE`
- `TxIE`
- `RmtEn`
- `EoB`
- `UMask`
- `Msk[28:0]`
- `MXtd`
- `MDir`

The following fields of a message object can be changed without clearing `MsgVal`:

- `ID[28:0]`
- `Xtd`
- `DLC[3:0]`
- `Data0[7:0] to Data7[7:0]`
- `TxRqst`
- `NewDat`
- `MsgLst`
- `IntPnd`

CAN Controller Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridge consist of the following regions:

- CAN Controller Module 0
- CAN Controller Module 1

Related Information

- **Introduction to Cyclone V Hard Processor System** on page 1-1
  The base addresses of all modules are also listed in the *Introduction to the Hard Processor System* chapter.

Protocol Group Register Descriptions

These registers are related to the CAN protocol controller in the CAN Core. They control the operating modes and the configuration of the CAN bit timing and provide status information.

Offset: 0x0

CCTRL on page 25-17
Control Register

CSTS on page 25-21
Status Register

CERC on page 25-24
Error Counter Register

CBT on page 25-25
This register is only writable if bits CCTRL.CCE and CCTRL.Init are set. The CAN bit time may be programed in the range of [4 .. 25] time quanta. The CAN time quantum may be programmed in the range of [1 .. 1024] CAN_CLK periods. For details see Application Note 001 "Configuration of Bit Timing". The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. TSeg1 is the sum of Prop_Seg and Phase_Seg1. TSeg2 is Phase_Seg2. Therefore the length of the bit time is (programmed values) [TSeg1 + TSeg2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

CIR on page 25-26
If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority, disregarding their chronological order. An interrupt remains pending until the CPU has cleared it. If IntID is different from 0x00 and CCTRL.MIL is set, the interrupt port CAN_INT_MO is active. The interrupt port remains active until IntID is back to value 0x00 (the cause of the interrupt is reset) or until CCTRL.MIL is reset. If CCTRL.ILE is set and CCTRL.MIL is reseted the Message Object interrupts will be routed to interrupt port CAN_INT_STATUS. The interrupt port remains active until IntID is back to value 0x00 (the cause of the interrupt is reset) or until CCTRL.MIL is set or CCTRL.ILE is reset. The Message Object's interrupt priority decreases with increasing message number. A message interrupt is cleared by clearing the Message Object's IntPnd bit.

CTR on page 25-27
The Test Mode is entered by setting bit CCTRL.Test to one. In Test Mode the bits EXL, Tx1, Tx0, LBack and Silent in the Test Register are writable. Bit Rx monitors the state of pin CAN_RXD and therefore is only readable. All Test Register functions are disabled when bit Test is reset to zero. Loop Back Mode and CAN_TXD Control Mode are hardware test modes, not to be used by application programs. Note: This register is only writable if bit CCTRL.Test is set.

CFR on page 25-29
The Function Register controls the features RAM_Initialisation and Power_Down also by application register. The CAN module can be prepared for Power_Down by setting the port CAN_CLKSTOP_REQ to one or writing to CFR.ClkStReq a one. The power down state is left by setting port CAN_CLKSTOP_REQ to zero or writing to CFR.ClkStReq a zero, acknowledged by CAN_CLKSTOP_ACK is going to zero as well as CFR.ClkStAck. The CCTRL.Init bit is left one and has to be written by the application to re-enable CAN transfers. Note: It's recommended to use either the ports CAN_CLKSTOP_REQ and CAN_CLKSTOP_ACK or the CCTRL.ClkStReq and CFR.ClkStAck. The application CFR.ClkStReq showsalso the actual status of the portCAN_CLKSTOP_REQ.

Bit	Name	Description	Access	Reset
19	DE2	DMA Enable for IF2 **Value** **Description** 0x0 Module DMA output port CAN_IF2DMA is always LOW. 0x1 Requesting a message object transfer from IF2 to Message RAM or vice versa with IF2CMR.DMAactive enabled the end of the transfer will be marked with setting port CAN_IF2DMA to one. The port remains one until first access to one of the IF2 registers.	RW	0x0
18	DE1	DMA Enable for IF1 **Value** **Description** 0x0 Module DMA output port CAN_IF1DMA is always LOW. 0x1 Requesting a message object transfer from IF1 to Message RAM or vice versa with IF1CMR.DMAactive enabled the end of the transfer will be marked with setting port CAN_IF1DMA to one. The port remains one until first access to one of the IF1 registers.	RW	0x0

Bit	Name	Description	Access	Reset
17	`MIL`	Message Object Interrupt Line Enable **Value** **Description** 0x0 Message Object Interrupt CAN_INT_MO is always LOW. If CCTRL.ILE is enabled all message object interrupts are routed to line CAN_INT_STATUS otherwise no message object interrupt will be visible. 0x1 Message object interrupts will set CAN_INT_MO to one, signal remains one until all pending interrupts are processed.	`RW`	`0x0`
7	`Test`	Test Mode Enable **Value** **Description** 0x0 Normal Operation. 0x1 Test Mode. Enables the write access to Test Register CTR.	`RW`	`0x0`
6	`CCE`	Configuration Change Enable **Value** **Description** 0x0 The CPU has no write access to the configuration registers. 0x1 The CPU has write access to the Bit Timing Register CBT (while CCTRL.Init = 1).	`RW`	`0x0`
5	`DAR`	Disable Automatic Retransmission **Value** **Description** 0x0 Automatic Retransmission of not successful messages enabled. 0x1 Automatic Retransmission disabled.	`RW`	`0x0`

Bit	Name	Description	Access	Reset
3	EIE	Error Interrupt Enable **Value** — **Description** 0x0 — CSTS.PER, CSTS.BOff and CSTS.EWarn flags will still be updated, but without affecting interrupt line CAN_INT_STATUS and Interrupt register CIR 0x1 — If CSTS.PER flag is one, or CSTS.BOff or CSTS.EWarn are changed, the interrupt line CAN_INT_STATUS gets active (if ILE=1) and CIR.StatusInt is set.	RW	0x0
2	SIE	Status Interrupt Enable **Value** — **Description** 0x0 — CSTS.RxOk, CSTS.TxOk and CSTS.LEC will still be updated, but without affecting interrupt line CAN_INT_STATUS and Interrupt register CIR. 0x1 — When a message transfer is successfully completed or a CAN bus error is detected, indicated by flags CSTS.RxOk, CSTS.TxOk and CSTS.LEC, the interrupt line CAN_INT_STATUS gets active (if ILE=1) and CIR.StatusInt is set.	RW	0x0
1	ILE	Module Interrupt Line Enable **Value** — **Description** 0x0 — Module Interrupt Line CAN_INT_STATUS is always LOW. 0x1 — Error and status interrupts (if CCTRL.EIE=1 and CCTRL.SIE=1) will set line CAN_INT_STATUS to one, signal remains one until all pending interrupts are processed. If MIL is disabled, the message object interrupts will also affect this interrupt line.	RW	0x0

Bit	Name	Description	Access	Reset
0	`Init`	Initialization Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to CCTRL.Init can be read back. Therefore the programmer has to assure that the previous value written to CCTRL.Init has been accepted by reading CCTRL.Init before setting CCTRL.Init to a new value.\n Note: The Bus_Off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or resetting CCTRL.Init. If the device goes Bus_Off, it will set CCTRL.Init of its own accord, stopping all bus activities. Once CCTRL.Init has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operations. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCTRL.Init, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to the Status Register, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the proceeding of the us_Off recovery sequence. **Value** — **Description** 0x0 — Normal Operation. 0x1 — Initialization is started.	`RW`	`0x1`

Bit	Name	Description	Access	Reset
8	PER	Parity Error Detected **Value** **Description** 0x0 No parity error detected since last read access. 0x1 The Parity CheckMechanism has detected a parity error in the Message RAM, this bit will be reset if Status Register is read	RO	0x0
7	BOff	Bus_Off Status **Value** **Description** 0x0 The CAN module is not Bus_Off. 0x1 The CAN module is in Bus_Off state.	RO	0x0
6	EWarn	Warning Status **Value** **Description** 0x0 Both error counters are below the error warning limit of 96. 0x1 At least one of the error counters in the EML has reached the error warning limit of 96.	RO	0x0
5	EPASS	Error Passive **Value** **Description** 0x0 The CAN Core is in the error active state. It normally takes part in bus communication and sends an active error flag when an error has been detected. 0x1 The CAN Core is in the error passive state as defined in the CAN Specification.	RO	0x0

Bit	Name	Description	Access	Reset
4	`RxOK`	Received a Message Successfully **Value** **Description** 0x0 Since this bit was read by the CPU, no message has been successfully received. This bit is never reset by CAN internal events. 0x1 Since this bit was last reset by a read access of the CPU, a message has been successfully received (independently of the result of acceptance filtering). This bit will be reset by reading the Status Register.	`RO`	`0x0`
3	`TxOK`	Transmitted a Message Successfully **Value** **Description** 0x0 Since this bit was last read by the CPU, no message has been successfully transmitted. This bit is never reset by CAN internal events. 0x1 Since this bit was last reset by a read access of the CPU, a message has been successfully (error free and acknowledged by at least one other node) transmitted. This bit will be reset by reading the Status Register.	`RO`	`0x0`

Bit	Name	Description	Access	Reset
2:0	LEC	The LEC field holds a code which indicates the type of the last error to occur on the CAN bus. This field will be cleared to 0 when a message has been transferred (reception or transmission) without error. **Value** — **Description** 0x0 — Set together with CSTS.RxOK or CSTS.TxOK. 0x1 — More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 0x2 — A fixed format part of a received frame has the wrong format. 0x3 — The message this CAN Core transmitted was not acknowledged by another node. 0x4 — During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value 1), but the monitored bus value was dominant. 0x5 — During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value 0), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 0x6 — The CRC checksum was incorrect in the message received, the CRC received for an incoming message does not match with the calculated CRC for the received data. 0x7 — Any read access to the Status Register re initializes the LEC to 7. When the LEC shows the value 7, no CAN bus event was detected since the last CPU read access to the Status Register.	RO	0x7

CTR Fields

Bit	Name	Description	Access	Reset
7	Rx	Monitors the actual value of the CAN_RXD pin. **Value** **Description** 0x0 The CAN bus is dominant (CAN_RXD = 0). 0x1 The CAN bus is recessive (CAN_RXD = 1).	RO	0x0
6:5	Tx	Controls CAN_TXD pin. Setting to non-zero disturbs message transfer. **Value** **Description** 0x0 Reset value, CAN_TXD is controlled by the CAN_Core. 0x1 Sample Point can be monitored at CAN_TXD pin. 0x2 CAN_TXD pin drives a dominant (0) value. 0x3 CAN_TXD pin drives a recessive (1) value.	RW	0x0
4	LBack	Loop Back Mode **Value** **Description** 0x0 Loop Back Mode is disabled. 0x1 Loop Back Mode is enabled.	RW	0x0
3	Silent	Silent Mode **Value** **Description** 0x0 Normal operation. 0x1 The CAN is in Silent Mode.	RW	0x0

CFR

The Function Register controls the features RAM_Initialisation and Power_Down also by application register. The CAN module can be prepared for Power_Down by setting the port CAN_CLKSTOP_REQ to one or writing to CFR.ClkStReq a one. The power down state is left by setting port CAN_CLKSTOP_REQ to zero or writing to CFR.ClkStReq a zero, acknowledged by CAN_CLKSTOP_ACK is going to zero as well as CFR.ClkStAck. The CCTRL.Init bit is left one and has to be written by the application to re-enable CAN transfers. Note: It's recommended to use either the ports CAN_CLKSTOP_REQ and CAN_CLKSTOP_ACK or the CCTRL.ClkStReq and CFR.ClkStAck. The application CFR.ClkStReq showsalso the actual status of the portCAN_CLKSTOP_REQ.

Bit	Name	Description	Access	Reset
3	`RAMinit`	Request for automatic RAM Initialization **Value** — **Description** 0x0 — No automatic RAM Initialization is requested, if once a ram initialization is started a write of a zero will be ignored. The Bit is cleared by hardware, after RAM Initialization is completed. 0x1 — Start automatic RAM Initialization. All message objects will be written with zeros and the parity bits will be set. The RAMInit Bit will return to zero after the RAM-Initialization process is completed. A RAM Initialization Request is only possible if CCTRL.Init is set. The duration of the automatic RAM Initialization is messagebuffer-size + 4 host_clock cycles.	RW	0x0

Message Handler Group Register Descriptions

These registers are related to the operation of the Message Handler. The Message Handler is a state machine that controls the data transfer between the single ported Message RAM and the CAN Core's Rx/Tx Shift Register. It also handles acceptance filtering and the interrupt setting as programmed in the Control and Configuration Registers.

Offset: 0x84

MOTRX on page 25-33
Reading this register allows the CPU to quickly detect if any of the transmission request bits in each of the MOTRA, MOTRB, MOTRC, and MOTRD Transmission Request Registers are set.

MOTRA on page 25-39
Transmission request bits for Message Objects 1 to 32. By reading the TxRqst bits, the CPU can check for which Message Object a Transmission Request is pending. The TxRqst bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Remote Frame or reset by the Message Handler after a successful transmission.

MOTRB on page 25-48
Transmission request bits for Message Objects 33 to 64. By reading the TxRqst bits, the CPU can check for which Message Object a Transmission Request is pending. The TxRqst bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Remote Frame or reset by the Message Handler after a successful transmission.

MOTRC on page 25-56
Transmission request bits for Message Objects 65 to 96. By reading the TxRqst bits, the CPU can check for which Message Object a Transmission Request is pending. The TxRqst bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Remote Frame or reset by the Message Handler after a successful transmission.

MOTRD on page 25-65
Transmission request bits for Message Objects 97 to 128. By reading the TxRqst bits, the CPU can check for which Message Object a Transmission Request is pending. The TxRqst bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Remote Frame or reset by the Message Handler after a successful transmission.

MONDX on page 25-74
Reading this register allows the CPU to quickly detect if any of the new data bits in each of the MONDA, MONDB, MONDC, and MONDD New Data Registers are set.

MONDA on page 25-79
New data bits for Message Objects 1 to 32. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/ reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

MONDB on page 25-90
New data bits for Message Objects 33 to 64. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/ reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

MONDC on page 25-101
New data bits for Message Objects 65 to 96. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/ reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

MONDD on page 25-112
New data bits for Message Objects 97 to 128. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/ reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

MOIPX on page 25-124
Reading this register allows the CPU to quickly detect if any of the interrupt pending bits in each of the MOIPA, MOIPB, MOIPC, and MOIPD Interrupt Pending Registers are set.

MOIPA on page 25-130
Interrupt pending bits for Message Objects 1 to 32. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

MOIPB on page 25-138
Interrupt pending bits for Message Objects 33 to 64. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

MOIPC on page 25-147
Interrupt pending bits for Message Objects 65 to 96. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

MOIPD on page 25-156
Interrupt pending bits for Message Objects 97 to 128. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

MOVALX on page 25-164
Reading this register allows the CPU to quickly detect if any of the message valid bits in each of the MOVALA, MOVALB, MOVALC, and MOVALD Message Valid Registers are set.

MOVALA on page 25-170
Message valid bits for Message Objects 1 to 32. By reading the MsgVal bits, the CPU can check for which Message Object is valid. The MsgVal bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers.

MOVALB on page 25-179
Message valid bits for Message Objects 33 to 64. By reading the MsgVal bits, the CPU can check for which Message Object is valid. The MsgVal bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers.

MOVALC on page 25-187
Message valid bits for Message Objects 65 to 96. By reading the MsgVal bits, the CPU can check for which Message Object is valid. The MsgVal bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers.

MOVALD on page 25-196
Message valid bits for Message Objects 97 to 128. By reading the MsgVal bits, the CPU can check for which Message Object is valid. The MsgVal bit of a specific Message Object can be set/reset by the CPU via the IFx Message Interface Registers.

MOTRX

Reading this register allows the CPU to quickly detect if any of the transmission request bits in each of the MOTRA, MOTRB, MOTRC, and MOTRD Transmission Request Registers are set.

Bit	Name	Description	Access	Reset
7	`NewDatB_3`	Each bit in this field is a logical OR of a byte of the MONDB register. Array index i corresponds to byte i of the MONDB register. **Value** **Description** 0x0 The Message Objects in the corresponding byte of MONDB don't have new data. 0x1 One or more of the Message Objects in the corresponding byte of MONDB have new data available.	`RO`	`0x0`
6	`NewDatB_2`	Each bit in this field is a logical OR of a byte of the MONDB register. Array index i corresponds to byte i of the MONDB register. **Value** **Description** 0x0 The Message Objects in the corresponding byte of MONDB don't have new data. 0x1 One or more of the Message Objects in the corresponding byte of MONDB have new data available.	`RO`	`0x0`
5	`NewDatB_1`	Each bit in this field is a logical OR of a byte of the MONDB register. Array index i corresponds to byte i of the MONDB register. **Value** **Description** 0x0 The Message Objects in the corresponding byte of MONDB don't have new data. 0x1 One or more of the Message Objects in the corresponding byte of MONDB have new data available.	`RO`	`0x0`
4	`NewDatB_0`	Each bit in this field is a logical OR of a byte of the MONDB register. Array index i corresponds to byte i of the MONDB register. **Value** **Description** 0x0 The Message Objects in the corresponding byte of MONDB don't have new data. 0x1 One or more of the Message Objects in the corresponding byte of MONDB have new data available.	`RO`	`0x0`

Bit	Name	Description	Access	Reset
3	`NewDatA_3`	Each bit in this field is a logical OR of a byte of the MONDA register. Array index i corresponds to byte i of the MONDA register. **Value** **Description** 0x0 The Message Objects in the corresponding byte of MONDA don't have new data. 0x1 One or more of the Message Objects in the corresponding byte of MONDA have new data available.	RO	0x0
2	`NewDatA_2`	Each bit in this field is a logical OR of a byte of the MONDA register. Array index i corresponds to byte i of the MONDA register. **Value** **Description** 0x0 The Message Objects in the corresponding byte of MONDA don't have new data. 0x1 One or more of the Message Objects in the corresponding byte of MONDA have new data available.	RO	0x0
1	`NewDatA_1`	Each bit in this field is a logical OR of a byte of the MONDA register. Array index i corresponds to byte i of the MONDA register. **Value** **Description** 0x0 The Message Objects in the corresponding byte of MONDA don't have new data. 0x1 One or more of the Message Objects in the corresponding byte of MONDA have new data available.	RO	0x0
0	`NewDatA_0`	Each bit in this field is a logical OR of a byte of the MONDA register. Array index i corresponds to byte i of the MONDA register. **Value** **Description** 0x0 The Message Objects in the corresponding byte of MONDA don't have new data. 0x1 One or more of the Message Objects in the corresponding byte of MONDA have new data available.	RO	0x0

MONDA

New data bits for Message Objects 1 to 32. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/ reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

RO	0x0

MONDD

New data bits for Message Objects 97 to 128. By reading the NewDat bits, the CPU can check for which Message Object the data portion was updated. The NewDat bit of a specific Message Object can be set/ reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception of a Data Frame or reset by the Message Handler at start of a transmission.

Array index i corresponds to byte i of the MOIPA register. **Value** **Description** 0x0 The Message Objects in the corresponding byte of MOIPA are not the source of an interrupt. 0x1 One or more of the Message Objects in the corresponding byte of MOIPA are the source an interrupt.	`RO`	`0x0`
1	`IntPndA_1`	Each bit in this field is a logical OR of a byte of the MOIPA register. Array index i corresponds to byte i of the MOIPA register. **Value** **Description** 0x0 The Message Objects in the corresponding byte of MOIPA are not the source of an interrupt. 0x1 One or more of the Message Objects in the corresponding byte of MOIPA are the source an interrupt.	`RO`	`0x0`

Bit	Name	Description	Access	Reset
0	IntPndA_0	Each bit in this field is a logical OR of a byte of the MOIPA register. Array index i corresponds to byte i of the MOIPA register. **Value** — **Description** 0x0 — The Message Objects in the corresponding byte of MOIPA are not the source of an interrupt. 0x1 — One or more of the Message Objects in the corresponding byte of MOIPA are the source an interrupt.	RO	0x0

MOIPA

Interrupt pending bits for Message Objects 1 to 32. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/ reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

MOIPD

Interrupt pending bits for Message Objects 97 to 128. By reading the IntPnd bits, the CPU can check for which Message Object an interrupt is pending. The IntPnd bit of a specific Message Object can be set/ reset by the CPU via the IFx Message Interface Registers or set by the Message Handler after reception or after a successful transmission of a frame. This will also affect the valid of IntID in the Interrupt Register.

Message Interface Group Register Descriptions

These registers provide indirect read and write access for the host CPU to the Message RAM. Buffers the data to be transferred to and from the RAM, avoiding conflicts between CPU accesses and CAN frame reception/transmission. The function of the two Interface Register sets is identical. The second interface register set is provided to serve application programming. Two groups of software drivers may defined, each group is restricted to the use of one of the Interface Register sets. The software drivers of one group may interrupt software drivers of the other group, but not of the same group. In a simple example, there is one Read_Message task that uses IF1 to get received messages from the Message RAM and there is one

Write_Message task that uses IF2 to write messages to be transmitted into the Message RAM. Both tasks may interrupt each other. Each set of Interface Registers consists controlled by their own Command Registers. The Command Mask Register specifies the direction of the data transfer and which parts of a Message Object will be transferred. The Command Request Register is used to select a Message Object in the Message RAM as target or source for the transfer and to start the action specified in the Command Mask Register.

Offset: `0x100`

IF1CMR on page 25-207
The control bits of the IF1/2 Command Register specify the transfer direction and select which portions of the Message Object should be transferred. A message transfer is started as soon as the CPU has written the message number to the low byte of the Command Request Register and IFxCMR.AutoInc is zero. With this write operation, the IFxCMR.Busy bit is automatically set to 1 to notify the CPU that a transfer is in progress. After a wait time of 2 to 8 HOST_CLK periods, the transfer between theInterface Register and the Message RAM has been completed and the IFxCMR.Busy bit is cleared to 0. The upper limit of the wait time occurs when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage. If the CPU writes to both Command Registers consecutively (requests a second transfer while another transfer is already in progress), the second transfer starts when the first one is completed. Note: While Busy bit of IF1/2 Command Register is one, IF1/2 Register Set is write protected.

IF1MSK on page 25-211
The Message Object Mask Bits together with the arbitration bits are used for acceptance filtering of incoming messages. Note: While IFxCMR.Busy bit is one, the IF1/2 Register Set is write protected.

IF1ARB on page 25-213
The Arbitration Registers ID28-0, Xtd, and Dir are used to define the identifier and type of outgoing messages and are used (together with the mask registers Msk28-0, MXtd, and MDir) for acceptance filtering of incoming messages. A received message is stored into the valid Message Object with matching identifier and Direction=receive (Data Frame) or Direction=transmit (Remote Frame). Extended frames can be stored only in Message Objects with Xtd = one, standard frames in Message Objects with Xtd = zero. If a received message (Data Frame or Remote Frame) matches with more than one valid Message Object, it is stored into that with the lowest message number.

IF1MCTR on page 25-214
The Arbitration Registers ID28-0, Xtd, and Dir are used to define the identifier and type of outgoing messages and are used (together with the mask registers Msk28-0, MXtd, and MDir) for acceptance filtering of incoming messages. A received message is stored into the valid Message Object with matching identifier and Direction=receive (Data Frame) or Direction=transmit (Remote Frame). Extended frames can be stored only in Message Objects with Xtd = one, standard frames in Message Objects with Xtd = zero. If a received message (Data Frame or Remote Frame) matches with more than one valid Message Object, it is stored into that with the lowest message number.

IF1DA on page 25-217
The data bytes of CAN messages are stored in the IF1/2 registers in the following order. In a CAN Data Frame, Data(0) is the first, Data(7) is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

IF1DB on page 25-218
The data bytes of CAN messages are stored in the IF1/2 registers in the following order. In a CAN Data Frame, Data(0) is the first, Data(7) is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

IF2CMR on page 25-219
The control bits of the IF1/2 Command Register specify the transfer direction and select which portions of the Message Object should be transferred. A message transfer is started as soon as the CPU has written the message number to the low byte of the Command Request Register and IFxCMR.AutoInc is zero. With this write operation, the IFxCMR.Busy bit is automatically set to 1 to notify the CPU that a transfer is in progress. After a wait time of 2 to 8 HOST_CLK periods, the transfer between theInterface Register and the Message RAM has been completed and the IFxCMR.Busy bit is cleared to 0. IF1CMR Fields

Bit	Name	Description	Access	Reset
29	ClrAutoInc	Clear the AutoInc bit without starting a transfer **Value** / **Description** 0x0 Has no effect to the other Bits of this Register. 0x1 Clear the AutoInc bit without starting a transfer, all other bits will be ignored.	RW	0x0

Bit	Name	Description	Access	Reset
23	WR1RD0	Write / Read Transfer **Value** **Description** 0x0 Transfer data from the Message Object addressed by IFxCMR.MONum into the selected IFx Message Buffer Registers. 0x1 Transfer data from the selected IFx Message Buffer Registers to the Message Object addressed by IFxCMR.MONum.	RW	0x0
22	Mask	Write Direction: 0= Mask bits unchanged. 1= transfer Identifier Mask + MDir + MXtd to Message Object. Read Direction: 0= Mask bits unchanged. 1= transfer Identifier Mask + MDir + MXtd to IFxMSK Register.	RW	0x0
21	Arb	Write Direction: 0= Arbitration bits unchanged. 1= transfer Identifier + Dir + Xtd + MsgVal to Message Object. Read Direction: 0= Arbitration bits unchanged. 1= transfer Identifier + Dir + Xtd + MsgVal to IFxARB Register.	RW	0x0
20	Control	Write Direction: 0= Control Bits unchanged. 1= transfer Control Bits to Message Object. Note: If IFxCMR.TxRqst/NewDat bit is set, bits IFxMCTR.TxRqst and IFxMCTR.NewDat will be ignored. Read Direction: 0= Control Bits unchanged. 1= transfer Control Bits to IFxMCTR Register.	RW	0x0
19	ClrIntPnd	Write Direction: Has no influence to Message Object at write transfer. Note: When writing to a Message Object, this bit is ignored and copying of IntPnd flag from IFx Control Register to Message RAM could only be controlled by IFxMTR.IntPnd bit. Read Direction: 0= IntPnd bit remains unchanged. 1= clear IntPnd bit in the Message Object.	RW	0x0

Bit	Name	Description	Access	Reset
18	TxRqstNewDat	Write Direction: 0= TxRqst and NewDat bit will be handled according IFxMCTR.NewDat bit and IFxMCTR.TxRqst bit. 1= set TxRqst and NewDat in Message Object to one Note: If a CAN transmission is requested by setting IFxCMR.TxRqst/NewDat, the TxRqst and NewDat bits in the Message Object will be set to one independently of the values in IFxMCTR. Read Direction: 0= NewDat bit remains unchanged. 1= clear NewDat bit in the Message Object. Note: A read access to a Message Object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the IFxMCTR always reflect the status before resetting them.	RW	0x0
17	DataA	Write Direction: 0= Data Bytes 0-3 unchanged. 1= transfer Data Bytes 0-3 to Message Object. Read Direction: 0= Data Bytes 0-3 unchanged. 1= transfer Data Bytes 0-3 to IFxDA.	RW	0x0
16	DataB	Write Direction: 0= Data Bytes 4-7 unchanged. 1= transfer Data Bytes 4-7 to Message Object. Read Direction: 0= Data Bytes 4-7 unchanged. 1= transfer Data Bytes 4-7 to IFxDB. Note: The speed of the message transfer does not depend on how many bytes are transferred.	RW	0x0
15	Busy	Busy Flag **Value** **Description** 0x0 Set to zero when read/write action has finished. 0x1 Set to one when writing to the IFxCMR.MONum. While bit is one, IFx Register Set is write protected.	RO	0x0

Bit	Name	Description	Access	Reset
14	`DMAactive`	Activation of DMA feature for subsequent internal IFx Register Set **Value** / **Description** 0x0 — DMA line leaves passive, independent of IFx activities. 0x1 — By writing to the Command Request Register, an internal transfer of Message Object Data between RAM and IFx will be initiated. When this transfer is complete and DMAactive bit was set, the CAN_IFxDMA line gets active. The DMAactive bit and port CAN_IFxDMA are staying active until first read or write access to one of the IFx registers. If AutoInc is set DMAactive will be left active, otherwise the bit is reset. Note: Due to auto reset feature of DMAactive bit if AutoInc is inactive, this bit has to be set for each subsequent DMA cycle separately. DMA line has to be enabled in CAN Control Register.	RW	0x0

Bit	Name	Description	Access	Reset
13	`AutoInc`	Automatic Increment of Message Object Number The behavior of the Message Object Number increment depends on the Transfer Direction, IFxCMR.WR1RD0. * Read: The first transfer will be initiated (Busy Bit will set) at write of IFxCMR.MONum. The Message Object Number will be incremented and the next Message Object will be transferred from Message Object RAM to Interface Registers after a read access of Data-Byte 7. * Write: The first as well as each other transfer will be started after write access to Data- Byte7. The Message Object Number will be incremented after successful transfer from the Interface Registers to the Message Object RAM. Always after successful transfer the Busy Bit will be reset. In combination with DMAactive the port CAN_IFxDMA is set, too. Note: If the direction is configured as Read a write access to Data-Byte 7 will not start any transfer, as well as if the direction is configured as Write a read access to Data-Byte 7 will not start any transfer. At transfer direction Read each read of Data-Byte 7 will start a transfer until IFxCMR.AutoInc is reset. To aware of resetting a NewDat bit of the following message object, the application has to reset IFxCMR.AutoInc before reading the Data-Byte 7 of the last message object which will be read. **Value** — **Description** 0x0 — AutoIncrement of Message Object Number disabled. 0x1 — AutoIncrement of Message Object Number enabled.	RW	0x0
7:0	`MONum`	0x01-0x80 Valid Message Number, the Message Object in the Message RAM is selected for data transfer (up to 128 MsgObj). 0x00 Not a valid Message Number, interpreted as 0x80. 0x81-0xFF Not a valid Message Number, interpreted as 0x01-0x7F. Note: When an invalid Message Number is written to IFxCMR.MONum which is higher than the last Message Object number, a modulo addressing will occur.When e.g. accessing Message Object 33 in a CAN module with 32 Message Objects only, the Message Object 1 will be accessed instead.	RW	0x1

IF1MSK

The Message Object Mask Bits together with the arbitration bits are used for acceptance filtering of incoming messages. Note: While IFxCMR.Busy bit is one, the IF1/2 Register Set is write protected.

IF2CMR

The control bits of the IF1/2 Command Register specify the transfer direction and select which portions of the Message Object should be transferred. A message transfer is started as soon as the CPU has written the message number to the low byte of the Command Request Register and IFxCMR.AutoInc is zero. With this write operation, the IFxCMR.Busy bit is automatically set to 1 to notify the CPU that a transfer is in progress. After a wait time of 2 to 8 HOST_CLK periods, the transfer between theInterface Register and the Message RAM has been completed and the IFxCMR.Busy bit is cleared to 0. The upper limit of the wait time occurs when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage. If the CPU writes to both Command Registers consecutively (requests a second transfer while another transfer is already in progress), the second transfer starts when the first one is completed. Note: While Busy bit of IF1/2 Command Register is one, IF1/2 Register Set is write protected.

On reception of a Remote Frame with matching identifier, the TxRqst bit of this Message Object is set (if RmtEn = one).	`RW`	`0x0`
28:0	`ID`	ID28 - ID0 29-bit Identifier (Extended Frame). ID28 - ID18 11-bit Identifier (Standard Frame).	`RW`	`0x0`

IF2MCTR

The Arbitration Registers ID28-0, Xtd, and Dir are used to define the identifier and type of outgoing messages and are used (together with the mask registers Msk28-0, MXtd, and MDir) for acceptance filtering of incoming messages. A received message is stored into the valid Message Object with matching identifier and Direction=receive (Data Frame) or Direction=transmit (Remote Frame). Extended frames can be stored only in Message Objects with Xtd = one, standard frames in Message Objects with Xtd = zero. If a received message (Data Frame or Remote Frame) matches with more than one valid Message Object, it is stored into that with the lowest message number.

Module Instance	Base Address	Register Address
`can0`	`0xFFC00000`	`0xFFC0012C`
`can1`	`0xFFC01000`	`0xFFC0112C`

Offset: `0x12C`

Access: `RW`

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NewDat RW 0x0	MsgLst RW 0x0	IntPnd RW 0x0	UMask RW 0x0	TxIE RW 0x0	RxIE RW 0x0	RmtEn RW 0x0	TxRqst RW 0x0	EoB RW 0x0	Reserved			DLC RW 0x0			

IF2MCTR Fields

Bit	Name	Description	Access	Reset
15	NewDat	New Data **Value** **Description** 0x0 No new data has been written into the data portion of this Message Object by the Message Handler since last time this flag was cleared by the CPU. 0x1 The Message Handler or the CPU has written new data into the data portion of this Message Object.	RW	0x0
14	MsgLst	Message Lost **Value** **Description** 0x0 No message lost since last time this bit was reset by the CPU. 0x1 The Message Handler stored a new message into this object when NewDat was still set, the CPU has lost a message.	RW	0x0
13	IntPnd	Interrupt Pending **Value** **Description** 0x0 This message object is not the source of an interrupt. 0x1 This message object is the source of an interrupt. The Interrupt Identifier in the Interrupt Register will point to this message object if there is no other interrupt source with higher priority.	RW	0x0

Bit	Name	Description	Access	Reset
12	UMask	Use Acceptance Mask **Value** — **Description** 0x0 — Acceptance formula1: (RTRRx == ~DIR) && (IDERx == IDE) && (IDRx == ID) 0x1 — (Msk28-0, MXtd, and MDir) for acceptance filtering, formula: ((RTRRx & MDIR) == (~DIR & MDIR)) && ((IDERx & MXtd) == (IDE & MXtd)) && ((IDRx & Msk) == (ID & Msk)) Note: If the UMask bit is set to one, the Message Object's mask bits have to be programmed during initialization of the Message Object before MsgVal is set to one.	RW	0x0
11	TxIE	Transmit Interrupt Enable **Value** — **Description** 0x0 — IntPnd will be left unchanged after the successful transmission of a frame. 0x1 — IntPnd will be set after a successful transmission of a frame.	RW	0x0
10	RxIE	Receive Interrupt Enable **Value** — **Description** 0x0 — IntPnd will be left unchanged after the successful reception of a frame. 0x1 — IntPnd will be set after a successful reception of a frame.	RW	0x0
9	RmtEn	Remote Enable **Value** — **Description** 0x0 — At the reception of a Remote Frame, TxRqst is left unchanged. 0x1 — At the reception of a Remote Frame, TxRqst is set.	RW	0x0

Bit	Name	Description	Access	Reset
8	`TxRqst`	Transmit Request **Value** — **Description** 0x0 — This Message Object is not waiting for transmission. 0x1 — The transmission of this Message Object is requested and is not yet done.	`RW`	`0x0`
7	`EoB`	Note: This bit is used to concatenate two or more Message Objects (up to 128) to build a FIFO Buffer. For single Message Objects (not belonging to a FIFO Buffer) this bit must always be set to one. **Value** — **Description** 0x0 — Message Object belongs to a FIFO Buffer Block and is not the last Message Object of that FIFO Buffer Block. 0x1 — Single Message Object or last Message Object of a FIFO Buffer Block.	`RW`	`0x0`
3:0	`DLC`	0-8 Data Frame has 0-8 data bytes. 9-15 Data Frame has 8 data bytes. Note: The Data Length Code of a Message Object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the Message Handler stores a data frame, it will write the DLC to the value given by the received message.	`RW`	`0x0`

IF2DA

The data bytes of CAN messages are stored in the IF1/2 registers in the following order. In a CAN Data Frame, Data(0) is the first, Data(7) is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

Module Instance	Base Address	Register Address
`can0`	`0xFFC00000`	`0xFFC00130`
`can1`	`0xFFC01000`	`0xFFC01130`

Offset: `0x130`

Access: `RW`

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Data3 RW 0x0								Data2 RW 0x0							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Data1 RW 0x0								Data0 RW 0x0							

IF2DA Fields

Bit	Name	Description	Access	Reset
31:24	Data3	4th data byte of a CAN Data Frame	RW	0x0
23:16	Data2	3rd data byte of a CAN Data Frame	RW	0x0
15:8	Data1	2nd data byte of a CAN Data Frame	RW	0x0
7:0	Data0	1st data byte of a CAN Data Frame	RW	0x0

IF2DB

The data bytes of CAN messages are stored in the IF1/2 registers in the following order. In a CAN Data Frame, Data(0) is the first, Data(7) is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

Module Instance	Base Address	Register Address
can0	0xFFC00000	0xFFC00134
can1	0xFFC01000	0xFFC01134

Offset: 0x134

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Data7 RW 0x0								Data6 RW 0x0							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Data5 RW 0x0								Data4 RW 0x0							

IF2DB Fields

Bit	Name	Description	Access	Reset
31:24	Data7	8th data byte of a CAN Data Frame	RW	0x0
23:16	Data6	7th data byte of a CAN Data Frame	RW	0x0

Bit	Name	Description	Access	Reset
15:8	`Data5`	6th data byte of a CAN Data Frame	`RW`	`0x0`
7:0	`Data4`	5th data byte of a CAN Data Frame	`RW`	`0x0`

Document Revision History

Table 25-4: Document Revision History

Date	Version	Changes
June 2014	2014.06.30	Add address map and register definitions
February 2014	2014.02.28	Maintenance release
December 2013	2013.12.30	Minor formatting updates
November 2012	1.2	• Minor updates. • Expanded reset section. • Expanded interrupts seciton.
May 2012	1.1	Added block diagram and system integration, functional description, programming model, and address map and register definitions sections.
January 2012	1.0	Initial release.

Introduction to the HPS Component 26

2014.06.30

cv_54026 Subscribe Send Feedback

The hard processor system (HPS) component is a soft component that you can instantiate in the FPGA fabric of the Cyclone® V SoC. It enables other soft components to interface with the HPS hard logic. The HPS component itself has a small footprint in the FPGA fabric, because its only purpose is to enable soft logic to connect to the extensive hard logic in the HPS.

For a description of the HPS and its integration into the system on a chip (SoC), refer to the *Cyclone V Device Datasheet*. For a description of HPS system architecture and features, refer to the *Introduction to the Hard Processor* chapter in volume 3 of the *Cyclone V Device Handbook* and the *CoreSight Debug and Trace* chapter in volume 3 of the *Cyclone V Device Handbook*.

The HPS supports the following peripheral architectures and features. The chapters that describe these features can be found on the Cyclone V documentation page.

- Clock manager
- Reset manager
- Interconnect
- HPS-FPGA AXI Bridge
- Cortex-A9 Microprocessor Unit Subsystem
- CoreSight Debug and Trace
- SDRAM Controller Subsystem
- On-Chip RAM and boot block ROM
- NAND Flash Controller
- SD/MMC Controller
- Quad SPI Flash Controller
- FPGA Manager Block Diagram and System Integration
- System Manager
- Scan Manager
- DMA Controller
- Ethernet Media Access Controller
- USB OTG Controller
- SPI Controller
- I^{2}C Controller
- UART Controller

- General-Purpose I/O Interface
- Timer
- Watchdog Timer

Instantiating the HPS Component 27

2014.06.30

cv_54027 Subscribe Send Feedback

You instantiate the hard processor system (HPS) component in Qsys. The HPS is available in the Qsys IP catalog under **Processor and Peripherals** > **Hard Processor Systems**. This chapter describes the parameters available in the HPS component parameter editor, which opens when you add or edit an HPS component.

Related Information

- **http://www.altera.com/literature/hb/cyclone-v/cv_51002.pdf**
  The HPS requires specific device targets. For a detailed list of supported devices, refer to the *Cyclone V Device Datasheet*.
- **http://www.altera.com/literature/hb/qts/quartusii_handbook.pdf**
  For general information about using Qsys, refer to the *Creating a System with Qsys* chapter in the *Quartus® II* Handbook.

FPGA Interfaces

The **FPGA Interfaces** tab is one of four tabs on the HPS Component. This tab contains several groups with the following parameters:

General Interfaces on page 27-1

AXI Bridges on page 27-3

FPGA-to-HPS SDRAM Interface on page 27-4

Reset Interfaces on page 27-5

DMA Peripheral Request on page 27-6

Interrupts on page 27-6

Related Information

Introduction to the HPS Component on page 26-1
For general information about interfaces, refer to *HPS Component Interfaces*.

General Interfaces

When enabled, the interfaces described in the following table become visible in the HPS component.

Table 27-1: General Parameters

Parameter Name	Parameter Description	Interface Name
Enable MPU standby and event signals	Enables interfaces that perform the following functions: • Notify the FPGA fabric that the microprocessor unit (MPU) is in standby mode. • Wake up an MPCore processor from a wait for event (WFE) state.	`h2f_mpu_events`
Enable general purpose signals	Enables a pair of 32-bit unidirectional general-purpose interfaces between the FPGA fabric and the FPGA manager in the HPS portion of the SoC device.	`h2f_gp`

Enable Debug APB interface	Enables debug interface to the FPGA, allowing access to debug components in the HPS. For more information, refer to the *CoreSight Debug and Trace* chapter.	`h2f_debug_apb`
		`h2f_debug_apb_sideband`
		`h2f_debug_apb_clock`
		`h2f_debug_apb_reset`

Enable System Trace Macrocell hardware events	Enables system trace macrocell (STM) hardware events, allowing logic inside the FPGA to insert messages into the trace stream. For more information, refer to the *CoreSight Debug and Trace* chapter.	`f2h_stm_hw_events`
Enable FPGA Cross Trigger interface	Enables the cross trigger interface (CTI), which allows trigger sources and sinks to interface with the embedded cross trigger (ECT). For more information, refer to the *CoreSight Debug and Trace* chapter.	`h2f_cti` `h2f_cti_clock`

Enable FPGA Trace Port Interface Unit	Enables an interface between the trace port interface unit (TPIU) and logic in the FPGA. The TPIU is a bridge between on-chip trace sources and a trace port. For more information, refer to the *CoreSight Debug and Trace* chapter.	`h2f_tpiu`
		`h2f_tpiu_clock_in`
		`h2f_tpiu_clock`

Parameter Name	Parameter Description	Interface Name
Enable boot from FPGA signals	Enable an input to the HPS indicating whether a preloader is available in on-chip memory of FPGA. This option also enables a separate input to the HPS indicating a fallback preloader is available in the FPGA memory. A fallback preloader is used when there is no valid preloader image found in flash memory. For more information, refer to *Appendix A: Booting and Configuration*.	`f2h_boot_from_fpga`
Enable HLGPI Interface	Enable a general purpose interface that is connected to the General Purpose I/O (GPIO) peripheral of HPS. This is an input-only interface with 14-bit width. This interface shares the I/O pins with the HPS DDR SDRAM controller.	`hps_io (hps_io_gpio_inst_HLGPI[0..13])`

Related Information

- **CoreSight Debug and Trace** on page 10-1
  Trace port interface unit (TPIU). Enabling the TPIU exposes trace signals to the device pins. Refer to the *CoreSight Debug and Trace* for more information.
- **Booting and Configuration Introduction** on page 30-1
  For detailed information about the HPS boot sequence, refer to the *Booting and Configuration*.

AXI Bridges

Table 27-2: Bridge Parameters

Parameter Name	Parameter Description	Interface Name
FPGA-to-HPS interface width	Enable or disable the FPGA-to-HPS interface; if enabled, set the data width to 32, 64, or 128 bits.	`f2h_axi_slave` `f2h_axi_clock`
HPS-to-FPGA interface width	Enable or disable the HPS-to-FPGA interface; if enabled, set the data width to 32, 64, or 128 bits.	`h2f_axi_master` `h2f_axi_clock`
Lightweight HPS-to-FPGA interface width	Enable or disable the lightweight HPS-to-FPGA interface. When enabled, the data width is 32 bits.	`h2f_lw_axi_master` `h2f_lw_axi_clock`

Note: To facilitate accessing these slaves from a memory-mapped master with a smaller address width, you can use the Altera® Address Span Extender.

Related Information

  Address span extender details
-

FPGA-to-HPS SDRAM Interface

In the **FPGA-to-HPS SDRAM Interface** table, use + or – to add or remove FPGA-to-HPS SDRAM interfaces.

You can add one or more SDRAM ports that make the HPS SDRAM subsystem accessible to the FPGA fabric.

Table 27-3: FPGA-to-HPS SDRAM Port and Interface Names

Port Name	Interface Name
f2h_sdram0	`f2h_sdram0_data` `f2h_sdram0_clock`
f2h_sdram1	`f2h_sdram1_data` `f2h_sdram1_clock`
f2h_sdram2	`f2h_sdram2_data` `f2h_sdram2_clock`
f2h_sdram3	`f2h_sdram3_data` `f2h_sdram3_clock`
f2h_sdram4	`f2h_sdram4_data` `f2h_sdram4_clock`
f2h_sdram5	`f2h_sdram5_data` `f2h_sdram5_clock`

The following table shows the parameters available for each SDRAM interface where the **Name** parameter denotes the interface name.

Table 27-4: FPGA-to-HPS SDRAM Interface Parameters

Parameter Name	Parameter Description
Name	Port name (auto assigned as shown in Table 27-3 table below)

Parameter Name	Parameter Description
Type	Interface type: • AXI-3 • Avalon-MM Bidirectional • Avalon-MM Write-only • Avalon-MM Read-only
Width	32, 64, 128, or 256

Note: You can configure the slave interface to a data width of 32, 64, 128, or 256 bits. To facilitate accessing this slave from a memory-mapped master with a smaller address width, you can use the *Altera Address Span Extender*.

Related Information

- **Using the Address Span Extender Component** on page 27-15
  Address span extender details
- **Functional Description—HPS Memory Controller** on page 11-1

Reset Interfaces

You can enable most resets on an individual basis.

Table 27-5: Reset Parameters

Parameter Name	Parameter Description	Interface Name
Enable HPS-to-FPGA cold reset output	Enable interface for HPS-to-FPGA cold reset output	`h2f_cold_reset`
Enable HPS warm reset handshake signals	Enable an additional pair of reset handshake signals allowing soft logic to notify the HPS when it is safe to initiate a warm reset in the FPGA fabric.	`h2f_warm_reset_handshake`
Enable FPGA-to-HPS debug reset request	Enable interface for FPGA-to-HPS debug reset request	`f2h_debug_reset_req`
Enable FPGA-to-HPS warm reset request	Enable interface for FPGA-to-HPS warm reset request	`f2h_warm_reset_req`
Enable FPGA-to-HPS cold reset request	Enable interface for FPGA-to-HPS cold reset request	`f2h_cold_reset_req`

Related Information

Reset Manager on page 3-1
For more information about the reset interfaces, refer to *Functional Description of the Reset Manager* in the *Reset Manager* chapter in the *Cyclone V Device Handbook, Volume 3*.

DMA Peripheral Request

You can enable each direct memory access (DMA) controller peripheral request ID individually. Each request ID enables an interface for FPGA soft logic to request one of eight logical DMA channels to the FPGA.

Related Information

DMA Controller on page 16-1

For more information, refer to the *DMA Controller* chapter in the *Cyclone V Device Handbook, Volume 3*.

Interrupts

Table 27-6: FPGA-to-HPS Interrupts Interface

Parameter Name	Parameter Description	Interface Name
Enable FPGA-to-HPS Interrupts	Enables interface for FPGA interrupt signals to the MPU (in the HPS).	f2h_irq0 f2h_irq1

You can enable the interfaces for each individual HPS peripheral interrupt to the FPGA. Table 27-7 shows the available HPS to FPGA interrupt interfaces and the corresponding parameters to enable them.

Table 27-7: HPS-to-FPGA Interrupts Interface

Parameter Name	Parameter Description	Interface Name
Enable CAN interrupts	Enables interface for HPS CAN controllers interrupt to the FPGA	`h2f_can0_interrupt` `h2f_can1_interrupt`
Enable clock peripheral interrupts	Enables interface for HPS clock manager and MPU wake-up interrupt signals to the FPGA	`h2f_clkmgr_interrupt` `h2f_mpuwakeup_interrupt`
Enable CTI interrupts	Enables interface for HPS cross-trigger interrupt signals to the FPGA	`h2f_cti_interrupt0` `h2f_cti_interrupt1`

Parameter Name	Parameter Description	Interface Name

Enable DMA interrupts	Enables interface for HPS DMA channels interrupt and DMA abort interrupt to the FPGA	`h2f_dma_interrupt0`
		`h2f_dma_interrupt1`
		`h2f_dma_interrupt2`
		`h2f_dma_interrupt3`
		`h2f_dma_interrupt4`
		`h2f_dma_interrupt5`
		`h2f_dma_interrupt6`
		`h2f_dma_interrupt7`
		`h2f_dma_abort_interrupt`

Enable EMAC interrupts	Enables interface for HPS Ethernet MAC controller interrupt to the FPGA	`h2f_emac0_interrupt` `h2f_emac1_interrupt`
Enable FPGA manager interrupts	Enables interface for the HPS FPGA manager interrupt to the FPGA	`h2f_fpga_man_interrupt`

Enable GPIO interrupts	Enables interface for the HPS general purpose IO (GPIO) interrupt to the FPGA	`h2f_gpio0_interrupt`
		`h2f_gpio1_interrupt`
		`h2f_gpio2_interrupt`

Enable I^{2}C-EMAC interrupts (for I2C2 and I2C3)	Enables interface for the HPS I^{2}C interrupt to the FPGA (I^{2}C used for EMAC media interface control)	`h2f_i2c_emac0_interrupt` `h2f_i2c_emac1_interrupt`

Enable I^{2}C peripheral interrupts (for I2C0 and I2C1)	Enables interface for the HPS I^{2}C interrupt to the FPGA (I^{2}C used for general purpose)	`h2f_i2c0 _interrupt`
		`h2f_i2c1_interrupt`

Enable L4 timer interrupts	Enables interface for the HPS SP timer interrupt to the FPGA. For more information, refer to the Timer Clock Characteristics table in the *Timer* chapter in the *Cyclone V Device Handbook, Volume 3.*	`h2f_l4sp0_interrupt` `h2f_l4sp1_interrupt`

Parameter Name	Parameter Description	Interface Name
Enable NAND interrupts	Enables interface for the HPS NAND controller interrupt to the FPGA	`h2f_nand_interrupt`
Enable OSC timer interrupts	Enables interface for the HPS OSC timer interrupt to the FPGA. For more information, refer to the Timer Clock Characteristics table in the *Timer* chapter in the *Cyclone V Device Handbook, Volume 3*.	`h2f_osc0_interrupt` `h2f_osc1_interrupt`
Enable Quad SPI interrupts	Enables interface for the HPS QSPI controller interrupt to the FPGA	`h2f_qspi_interrupt`
Enable SD/MMC interrupts	Enables interface for the HPS SD/MMC controller interrupt to the FPGA	`h2f_sdmmc_interrupt`
Enable SPI master interrupts	Enables interface for the HPS SPI master controller interrupt to the FPGA	`h2f_spi0_interrupt` `h2f_spi1_interrupt`
Enable SPI slave interrupts	Enables interface for the HPS SPI slave controller interrupt to the FPGA	`h2f_spi2_interrupt` `h2f_spi3_interrupt`
Enable UART interrupts	Enables interface for the HPS UART controller interrupt to the FPGA	`h2f_uart0_interrupt` `h2f_uart1_interrupt`
Enable USB interrupts	Enables interface for the HPS USB controller interrupt to the FPGA	`h2f_usb0_interrupt` `h2f_usb1_interrupt`
Enable watchdog interrupts	Enables interface for the HPS watchdog interrupt to the FPGA	`h2f_wdog0_interrupt` `h2f_wdog1_interrupt`

Configuring Peripheral Pin Multiplexing

The **Peripheral Pin Multiplexing** tab is one of four tabs on the HPS Component. This tab contains several groups with the following parameters:

Configuring Peripherals on page 27-9

Connecting Unassigned Pins to GPIO on page 27-10

Using Unassigned IO as LoanIO on page 27-10
You can utilize unused HPS IOs as LoanIO, which is directly driven by the FPGA and can be used as input, output, or bi-directional.

Resolving Pin Multiplexing Conflicts on page 27-10
Use the **Peripherals MUX Table** to view pins with invalid multiple assignments.

Route Peripheral Signals to FPGA on page 27-11
You can route the peripheral signals to the FPGA fabric and assign them to the FPGA I/O pins.

Configuring Peripherals

The **Peripheral Pin Multiplexing** tab contains a group of parameters for each available type of peripheral. You can enable one or more instances of each peripheral type by selecting an HPS I/O pin set for each instance. When enabled, some peripherals also have a mode settings specific to their functions.

When you assign a peripheral to an HPS I/O pin set, the corresponding peripheral is highlighted in the **Peripherals MUX Table** at the end of **Peripheral Pin Multiplexing** tab. The other unused peripheral pin set remains un-highlighted in the table.

Each list in the **Peripheral Pin Multiplexing** tab has a hint describing in detail the options available in the list. The hint for each mode list shows the signals used by each available mode. View each hint by hovering over the corresponding mode list.

You can enable the following types of peripherals. For details of peripheral-specific settings, refer to the chapter for each peripheral:

Related Information

- CAN Controller Introduction on page 25-1

Connecting Unassigned Pins to GPIO

For pins that are not assigned to any peripherals, you can assign them to the GPIO peripheral by clicking on the corresponding GPIO push button in the table. Click on the selected push button to remove GPIO pin assignment. The table also shows the GPIO bit number that correlates to the I/O pins.

Using Unassigned IO as LoanIO

You can utilize unused HPS IOs as LoanIO, which is directly driven by the FPGA and can be used as input, output, or bi-directional.

Each LOANIO port has an input, output, and output enable, which directly controls the HPS IO functions. The LoanIO only operates when the HPS registers have been set up in the pre-loader to allow their operation. The LoanIO are asynchronous, thus no clocking is required.

Use the following steps to enable the LoanIO signals:

1. Select **Peripheral Pins Multiplexing** tap in the HPS Megawizard.
2. Choose the corresponding LoanIO pins from the **Peripherals Mux Table**, click the push button to select/unselect it.
3. Export the peripheral signals out of the Qsys system.
4. In the Quartus II software, connect the user logic to the LoanIO interface to drive the HPS IOs.

Table 27-8: Generated Conduit Signal Interface

Conduit Name	Direction	Declarations
._hps_io_gpio_inst_LOANIOXX	Bi-direction	User must declare as a top-level pin; pin assignment is hardcoded following the HPS IO location.
._h2f_loan_io_in[48]	Out	HPS IO data input signal, output to FPGA user logic.
._h2f_loan_io_out[48]	In	HPS IO data output signal, input from FPGA user logic.
._h2f_loan_io_oe[48]	In	HPS IO data output enable signal, input from FPGA user logic.

Resolving Pin Multiplexing Conflicts

Use the **Peripherals MUX Table** to view pins with invalid multiple assignments.

Pins that have multiple peripherals assigned to them are highlighted in red color with the conflicting peripherals in boldface font style. Solve the multiplexing conflicts by de-selecting peripherals that are assigned to the pins, leaving only one peripheral, which is needed.

[48] Qsys will generate a full signal array for `h2f_loan_io_in, h2f_loan_io_out`, and `h2f_loan_io_oe`. You must assign user logic to the specific signal array. For example, you have triggered LoanIO 40, so its respective signal array is `h2f_loan_io_in[40], h2f_loan_io_out[40]`, and `h2f_loan_io_oe[40]`.

Route Peripheral Signals to FPGA

You can route the peripheral signals to the FPGA fabric and assign them to the FPGA I/O pins.

The following steps show you how to enable the peripheral signals:

1. Select FPGA in the peripheral pin multiplexing selection drop-down box.
2. Export the peripheral signals out of Qsys system.
3. In the Quartus II software, connect the signals to the FPGA I/O pins.

Configuring HPS Clocks

The **HPS Clocks** tab is one of four tabs on the HPS Component. This tab contains several groups with the following parameters:

User Clocks on page 27-11

PLL Reference Clocks on page 27-12

Peripheral FPGA Clocks on page 27-12

User Clocks

When you enable a user clock, you must manually enter its maximum frequency for timing analysis. The TimeQuest Timing Analyzer has no other information about how software running on the HPS configures the phase-locked loop (PLL) outputs. Each possible clock, including clocks that are available from peripherals, has its own parameter for describing the clock frequency.

Related Information

Selecting PLL Output Frequency and Phase on page 27-14

User Clock Parameters

The frequencies that you provide are the maximum expected frequencies. The actual clock frequencies can be modified through the register interface, for example by software running on the microprocessor unit (MPU). For further details, refer to *Selecting PLL Output Frequency and Phase*.

Table 27-9: User Clock Parameters

Parameter Name	Parameter Description	Clock Interface Name
Enable HPS-to-FPGA user 0 clock	Enable main PLL from HPS-to-FPGA	`h2f_user0_clock`
User 0 clock frequency	Specify the maximum expected frequency for the main PLL	
Enable HPS-to-FPGA user 1 clock	Enable peripheral PLL from HPS-to-FPGA	`h2f_user1_clock`
User 1 clock frequency	Specify the maximum expected frequency for the peripheral PLL	

Parameter Name	Parameter Description	Clock Interface Name
Enable HPS-to-FPGA user 2 clock	Enable SDRAM PLL from HPS-to-FPGA	`h2f_user2_clock`
User 2 clock frequency	Specify the maximum expected frequency for the SDRAM PLL	

Related Information

Selecting PLL Output Frequency and Phase on page 27-14

Clock Frequency Usage

The clock frequencies you provide are reported in a Synopsys Design Constraints File (**.sdc**) generated by Qsys.

Peripheral FPGA Clocks

Table 27-11: Peripheral FPGA Clock Parameters

Parameter Name	Parameter Description
EMAC 0 (emac0_md_clk clock frequency)	If EMAC 0 peripheral is routed to FPGA, use this field to specify EMAC 0 MDIO clock frequency

Parameter Name	Parameter Description
EMAC 0 (emac0_gtx_clk clock frequency)	If EMAC 0 peripheral is routed to FPGA, use this field to specify EMAC 0 transmit clock frequency
EMAC 1 (emac1_md_clk clock frequency)	If EMAC 1 peripheral is routed to FPGA, use this field to specify EMAC 1 MDIO clock frequency
EMAC 1 (emac1_gtx_clk clock frequency)	If EMAC 1 peripheral is routed to FPGA, use this field to specify EMAC 1 transmit clock frequency
QSPI (qspi_sclk_out clock frequency)	If QSPI peripheral is routed to FPGA, use this field to specify QSPI serial clock frequency
SPIM 0 (spim0_sclk_out clock frequency)	If SPI master 0 peripheral is routed to FPGA, use this field to specify SPI master 0 output clock frequency
SPIM 1 (spim1_sclk_out clock frequency)	If SPI master 1 peripheral is routed to FPGA, use this field to specify SPI master 1 output clock frequency
I^{2}C0 (i2c0_clk clock frequency)	If I^{2}C 0 peripheral is routed to FPGA, use this field to specify I^{2}C 0 output clock frequency
I^{2}C1 (i2c1_clk clock frequency)	If I^{2}C 1 peripheral is routed to FPGA, use this field to specify I^{2}C 1 output clock frequency
I^{2}C2 (i2c2_clk clock frequency)	If I^{2}C 2 peripheral is routed to FPGA, use this field to specify I^{2}C 2 output clock frequency
I^{2}C3 (i2c3_clk clock frequency)	If I^{2}C 3 peripheral is routed to FPGA, use this field to specify I^{2}C 3 output clock frequency

Configuring the External Memory Interface

The **SDRAM** tab is one of four tabs on the HPS component. This tab contains the PLL output frequency and phase group.

The HPS supports one memory interface implementing double data rate 2 (DDR2), double data rate 3 (DDR3), and low-power double data rate 2 (LPDDR2) protocols. The interface can be up to 40 bits wide with optional error correction code (ECC).

Configuring the HPS SDRAM controller is similar to configuring any other Altera SDRAM controller. There are several important differences:

- The HPS parameter editor supports all SDRAM protocols with one tab. When you parameterize the SDRAM controller, you must specify the memory protocol: DDR2, DDR3, or LPDDR2.

To select the memory protocol, select DDR2, DDR3, or LPDDR2 from the **SDRAM Protocol** list in the **SDRAM** tab. After you select the protocol, settings not applicable to that protocol are disabled.

- Many HPS SDRAM controller settings are the same as for Altera’s dedicated DDR2, DDR3, and LPDDR2 controllers. This section only describes SDRAM parameters that are specific to the HPS component.
- Because the HPS memory controller is not configurable through the Quartus II software, the Controller and Diagnostic tabs are not present in the HPS parameter editor.
- Some settings, such as the controller settings, are not included because they can only be configured through the register interface, for example by software running on the MPU.
- Unlike the memory interface clocks in the FPGA, the memory interface clocks for the HPS are initialized by the boot-up code using values provided by the configuration process. You can accept the values provided by UniPHY, or you can use your own PLL settings, as described in *Selecting PLL Output Frequency and Phase*.

Note: The HPS does not support external memory interface (EMIF) synthesis generation, compilation, or timing analysis.

The HPS memory controller cannot be bonded with a memory controller on the FPGA portion of the device.

For detailed information about SDRAM controller parameters, refer to the following chapters:

Selecting PLL Output Frequency and Phase

You select PLL output frequency and phase with controls in the **PHY Settings** tab. In the HPS, PLL frequencies and phases are set by software at system startup. A PLL might not be able to produce the exact frequency that you specify in **Memory clock frequency**. Normally, the Quartus II software sets **Achieved memory clock frequency** to the closest achievable frequency, using an algorithm that tries to balance frequency accuracy against clock jitter. This clock frequency is used for timing analysis by the TimeQuest analyzer.

It is possible to use a different software algorithm for configuring the PLLs. You can force the **Achieved memory clock frequency** box to take on the same value as **Memory clock frequency**, by turning on **Use specified frequency instead of calculated frequency** in the **PHY Settings** tab, under **Clocks**.

Note: If you turn on **Use specified frequency instead of calculated frequency**, the Quartus II software assumes that the value in the **Achieved memory clock frequency** box is correct. If it is not, timing analysis results are incorrect.

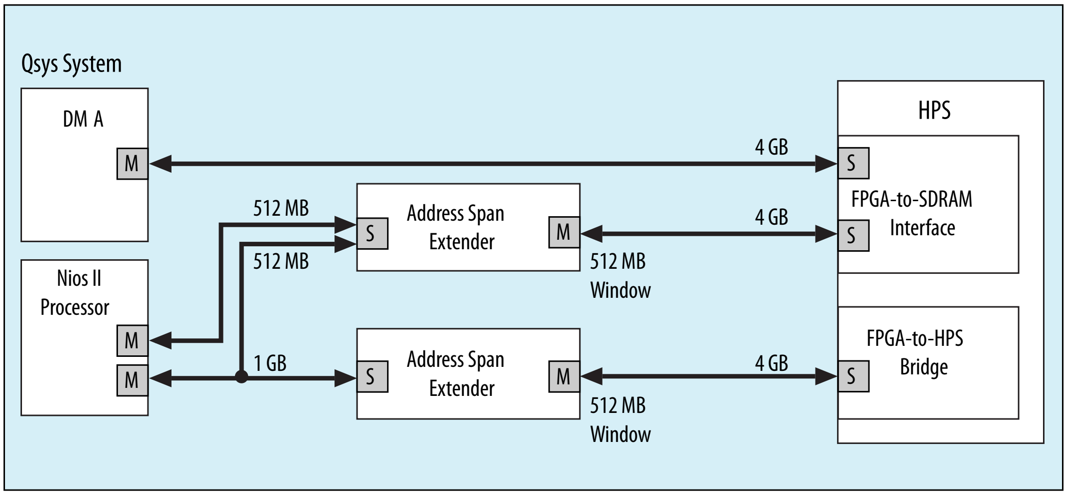
Using the Address Span Extender Component

The FPGA-to-HPS bridge and FPGA-to-HPS SDRAM memory-mapped interfaces expose their entire 4 GB address spaces to the FPGA fabric. The Address Span Extender component provides a memory-mapped window into the address space that it masters. Using the address span extender, you can expose portions of the HPS memory space without needing to expose the entire 4 GB address space.

You can use the address span extender between a soft logic master and an FPGA-to-HPS bridge or FPGA-to-HPS SDRAM interface. This component reduces the number of address bits required for a master to address a memory-mapped slave interface located in the HPS.

Figure 27-1: Address Span Extender Components

Two address span extender components used in a system with the HPS.



You can also use the address span extender in the HPS-to-FPGA direction, for slave interfaces in the FPGA. In this case, the HPS-to-FPGA bridge exposes a limited, variable address space in the FPGA, which can be paged in using the address span extender.

For example, suppose that the HPS-to-FPGA bridge has a 1 GB span, and the HPS needs to access three independent 1 GB memories in the FPGA portion of the device. To achieve this, the HPS programs the address span extender to access one SDRAM (1 GB) in the FPGA at a time. This technique is commonly called paging or windowing.

Related Information

Qsys interconnect and System Design Components
For more information about the address span extender, refer to *Bridges* in the *Qsys* Interconnect and System Design Components chapter in the *Quartus® II* Handbook.

Generating and Compiling the HPS Component

The process of generating and compiling an HPS design is very similar to the process for any other Qsys project. Perform the following steps:

1. Generate the design with Qsys. The generated files include an **.sdc** file containing clock timing constraints. If simulation is enabled, simulation files are also generated.
2. Add *<qsys_system_name>.qip* to the Quartus II project. *<qsys_system_name>.qip* is the Quartus II IP File for the HPS component, generated by Qsys.
3. Perform analysis and synthesis with the Quartus II software.
4. Assign constraints to the SDRAM component. When Qsys generates the HPS component (step 1), it generates the pin assignment Tcl Script File (**.tcl**) to perform memory assignments. The script file name is **<qsys_system_name>_pin_assignments.tcl**, where <qsys_system_name> is the name of your Qsys system. Run this script to assign constraints to the SDRAM component.

   Note: For information about running the pin assignment script, refer to “MegaWizard Plug-In Manager Flow” in the *Implementing and* Parameterizing Memory IP chapter in the *External Memory Interface Handbook.*

   You do not need to specify pin assignments other than memory assignments. When you configure pin multiplexing as described in *Configuring Peripheral Pin Multiplexing*, you implicitly make pin assignments for all HPS peripherals. Each peripheral is routed exclusively to the pins you specify. HPS I/O signals are exported to the top level of the Qsys design, with information enabling the Quartus II software to make pin assignments automatically.

   You can view and modify the assignments in the **Peripheral Pin Multiplexing** tab. You can also view the assignments in the Quartus fitter report.
5. Compile the design with the Quartus II software.
6. Optionally back-annotate the SDRAM pin assignments, to eliminate pin assignment warnings the next time you compile the design.

Document Revision History

Table 27-12: Document Revision History

Date	Version	Changes
June 2014	2014.06.30	• Updated the Instantiating the HPS Component section. • Added the Using Unassigned IO as LoanIO section.
February 2014	2014.02.28	• Add interfaces to tables • Add parameters to General Parameters table
December 2013	1.2	Maintenance release.
November 2012	1.1	• Added debug interfaces • Added boot options • Corrected slave address width • Corrected SDRAM interface widths • Added TPIU peripheral • Added .sdc file generation • Added .tcl script for memory assignments
June 2012	1.0	Initial release.
May 2012	0.1	Preliminary draft.

HPS Component Interfaces 28

2014.06.30

cv_54028 Subscribe Send Feedback

This chapter describes the interfaces, including clocks and resets, implemented by the hard processor system (HPS) component.

The majority of the resets can be enabled on an individual basis. The exception is the `h2f_reset` interface, which is always enabled.

You must declare the clock frequency of each HPS-to-FPGA clock for timing purposes. Each possible clock, including ones that are available from peripherals, has its own parameter for describing the clock frequency. Declaring the clock frequency for HPS-to-FPGA clocks specifies how you plan to configure the PLLs and peripherals, to enable TimeQuest to accurately estimate system timing. It has no effect on PLL settings.

Memory-Mapped Interfaces

FPGA-to-HPS Bridge

Table 28-1: FPGA-to-HPS Bridges and Clocks

Interface Name	Description	Associated Clock Interface
`f2h_axi_slave`	FPGA-to-HPS AXI slave interface	`f2h_axi_clock`

The FPGA-to-HPS interface is a configurable data width AXI slave allowing FPGA masters to issue transactions to the HPS. This interface allows the FPGA fabric to access the majority of the HPS slaves. This interface also provides a coherent memory interface.

The FPGA-to-HPS interface is an AXI-3 compliant interface with the following features:

- Configurable data width: 32, 64, or 128 bits
- Accelerator Coherency Port (ACP) sideband signals
- HPS-side AXI bridge to manage clock crossing, buffering, and data width conversion

Other interface standards in the FPGA fabric, such as connecting to Avalon® Memory-Mapped (Avalon-MM) interfaces, can be supported through the use of soft logic adapters. The Qsys system integration tool automatically generates adapter logic to connect AXI to Avalon-MM interfaces.

This interface has an address width of 32 bits. To access existing Avalon-MM/AXI masters, you can use the Altera® Address Span Extender.

Related Information

ACP Sideband Signals

For communication with the ACP on the microprocessor unit (MPU) subsystem, AXI sideband signals are used to describe the inner cacheable attributes for the transaction.

Related Information

Cortex-A9 MPCore on page 9-4
For more information about the ACP sideband signals, refer to the *Cortex-A9 MPU Subsystem* chapter.

HPStoFPGA and Lightweight HPS-to-FPGA Bridges

Table 28-2: HPStoFPGA and Lightweight HPS-to-FPGA Bridges and Clocks

Interface Name	Description	Associated Clock Interface
h2f_axi_master	HPS-to-FPGA AXI master interface	h2f_axi_clock
h2f_lw_axi_master	HPS-to-FPGA lightweight AXI master interface	h2f_lw_axi_clock

The HPS-to-FPGA interface is a configurable data width AXI master (32-, 64-, or 128-bit) that allows HPS masters to issue transactions to the FPGA fabric.

The lightweight HPS-to-FPGA interface is a 32-bit AXI master that allows HPS masters to issue transactions to the FPGA fabric.

Both HPS-to-FPGA interfaces are AXI-3 compliant. The HPS-side AXI bridges manage clock crossing, buffering, and data width conversion where necessary.

Other interface standards in the FPGA fabric, such as connecting to Avalon-MM interfaces, can be supported through the use of soft logic adaptors. The Qsys system integration tool automatically generates adaptor logic to connect AXI to Avalon-MM interfaces.

Each AXI bridge accepts a clock input from the FPGA fabric and performs clock domain crossing internally. The exposed AXI interface operates on the same clock domain as the clock supplied by the FPGA fabric.

Related Information

- **Clocks** on page 28-4

  For more information, refer to the *HPS FPGA AXI Bridges Component* chapter.

FPGA-to-HPS SDRAM Interface

The FPGA-to-HPS SDRAM interface is a direct connection between the FPGA fabric and the HPS SDRAM controller. This interface is highly configurable, allowing a mix between number of ports and port width. The interface supports both AXI-3 and Avalon-MM protocols.

Table 28-3: FPGA-to-HPS SDRAM Interfaces and Clocks

Interface Name	Description	Associated Clock Interface
`f2h_sdram0_data`	SDRAM AXI or Avalon-MM port 0	`f2h_sdram0_clock`
`f2h_sdram1_data`	SDRAM AXI or Avalon-MM port 1	`f2h_sdram1_clock`
`f2h_sdram2_data`	SDRAM AXI or Avalon-MM port 2	`f2h_sdram2_clock`
`f2h_sdram3_data`	SDRAM AXI or Avalon-MM port 3	`f2h_sdram3_clock`
`f2h_sdram4_data`	SDRAM AXI or Avalon-MM port 4	`f2h_sdram4_clock`
`f2h_sdram5_data`	SDRAM AXI or Avalon-MM port 5	`f2h_sdram5_clock`

The FPGA-to-HPS SDRAM interface is a configurable interface to the multi-port SDRAM controller.

The total data width of all interfaces is limited to a maximum of 256 bits in the read direction and 256 bits in the write direction. The interface is implemented as four 64-bit read ports and four 64-bit write ports. As a result, the minimum data width used by the interface is 64 bits, regardless of the number or type of interfaces.

You can configure this interface the following ways:

- AXI-3 or Avalon-MM protocol
- Number of interfaces
- Data width of interfaces

The FPGA-to-HPS SDRAM interface supports six command ports, allowing up to six Avalon-MM interfaces or three bidirectional AXI interfaces.

Each command port is available either to implement a read or write command port for AXI, or to form part of an Avalon-MM interface.

You can use a mix of Avalon-MM and AXI interfaces, limited by the number of command/data ports available. Some AXI features are not present in Avalon-MM interfaces.

This interface has an address width of 32 bits. To access existing Avalon-MM/AXI masters, you can use the Altera Address Span Extender.

  For information about the address span extender, refer to “Using the Address Span Extender Component” in the *Instantiating the HPS Component* chapter.

Clocks

The HPS-to-FPGA clock interface supplies physical clocks and resets to the FPGA. These clocks and resets are generated in the HPS.

Alternative Clock Inputs to HPS PLLs

This section lists alternative clock inputs to HPS PLLs.

- `f2h_periph_ref_clock`—FPGA-to-HPS peripheral PLL reference clock. You can connect this clock input to a clock in your design that is driven by the clock network on the FPGA side.
- `f2h_sdram_ref_clock`—FPGA-to-HPS SDRAM PLL reference clock. You can connect this clock to a clock in your design that is driven by the clock network on the FPGA side.

User Clocks

A user clock is a PLL output that is connected to the FPGA fabric rather than the HPS. You can connect a user clock to logic that you instantiate in the FPGA fabric.

- `h2f_user0_clock`—HPS-to-FPGA user clock, driven from main PLL
- `h 2f_user1_clock`—HPS-to-FPGA user clock, driven from peripheral PLL
- `h2f_user2_clock`—HPS-to-FPGA user clock, driven from SDRAM PLL

AXI Bridge FPGA Interface Clocks

The AXI interface has an asynchronous clock crossing in the FPGA-to-HPS bridge. The FPGA-to-HPS and HPS-to-FPGA interfaces are synchronized to clocksgenerated in the FPGA fabric. These interfaces can be asynchronous to one another. The SDRAM controller’s multiport front end (MPFE) transfers the data between the FPGA and HPS clock domains.

- `f2h_axi_clock`—AXI slave clock for FPGA-to-HPS bridge, generated in FPGA fabric
- `h2f_axi_clock`—AXI master clock for HPS-to-FPGA bridge, generated in FPGA fabric
- `h2f_lw_axi_clock`—AXI master clock for lightweight HPS-to-FPGA bridge, generated in FPGA fabric

SDRAM Clocks

You can configure the HPS component with up to six FPGA-to-HPS SDRAM clocks.

Each command channel to the SDRAM controller has an individual clock source from the FPGA fabric. The interface clock is always supplied by the FPGA fabric, with clock crossing occurring on the HPS side of the boundary.

The FPGA-to-HPS SDRAM clocks are driven by soft logic in the FPGA fabric.

- `f2h_sdram0_clock`—SDRAM clock for port 0
- `f2h_sdram1_clock`—SDRAM clock for port 1
- `f2h_sdram2_clock`—SDRAM clock for port 2
- `f2h_sdram3_clock`—SDRAM clock for port 3
- `f2h_sdram4_clock`—SDRAM clock for port 4
- `f2h_sdram5_clock`—SDRAM clock for port 5

Peripheral FPGA Clocks

The HPS peripheral clocks are exposed when the peripheral signals are routed to the FPGA.

Table 28-4: Peripheral FPGA Clocks

Clock Name	Description
`emac_md_clk`	Ethernet PHY management interface clock
`emac_gtx_clk`	Ethernet transmit clock that is used by the PHY in GMII mode
`emac_rx_clk_in`	Ethernet MAC reference clock from the PHY
`emac_tx_clk_in`	Ethernet MAC uses this clock input for TX reference
`emac_ptp_ref_clock`	Ethernet timestamp precision time protocol (PTP) reference clock
`qspi_sclk_out`	QSPI master clock output
`spim_sclk_out`	SPI master serial clock output
`spis_sclk_in`	SPI slave serial clock input
`i2c_clk`	I^{2}C outgoing clock (part of the SCL bidirectional pin signals)
`i2c_scl_in`	I^{2}C incoming clock (part of the SCL bidirectional pin signals)

Resets

This section describes the reset interfaces to the HPS component.

Related Information

Reset Manager on page 3-1

For details about the HPS reset sequences, refer to the *Functional Description of the Reset Manager* in the *Reset Manager* chapter .

HPS-to-FPGA Reset Interfaces

The following interfaces allow the HPS to reset soft logic in the FPGA fabric:

- `h2f_reset`—HPS-to-FPGA cold and warm reset
- `h2f_cold_reset`—HPS-to-FPGA cold reset
- `h2f_warm_reset_handshake`—Warm reset request and acknowledge interface between HPS and FPGA

HPS External Reset Sources

The following interfaces allow soft logic in the FPGA fabric to reset the HPS:

- `f2h_cold_reset_req`—FPGA-to-HPS cold reset request
- `f2h_warm_reset_req`—FPGA-to-HPS warm reset request
- `f2h_dbg_reset_req`—FPGA-to-HPS debug reset request

Peripheral Reset Interfaces

The following are Ethernet reset interfaces, that can be used when the Ethernet is routed to the FPGA:

- `emac_tx_reset`— Ethernet transmit clock reset output used to reset external PHY TX clock domain logic
- `emac_rx_reset`— Ethernet receive clock reset output used to reset external PHY RX clock domain logic

Debug and Trace Interfaces

Trace Port Interface Unit

The TPIU is a bridge between on-chip trace sources and a trace port.

- `h2f_tpiu`
- `h2f_tpiu_clock_in`
- `h2f_tpiu_clock`

FPGA System Trace Macrocell Events Interface

The system trace macrocell (STM) hardware events allow logic in the FPGA to insert messages into the trace stream.

- `f2h_stm_hw_events`

FPGA Cross Trigger Interface

The cross trigger interface (CTI) allows trigger sources and sinks to interface with the embedded cross trigger (ECT).

- `h2f_cti`
- `h2f_cti_clock`

Debug APB Interface

The debug Advanced Peripheral Bus (APB™) interface allows debug components in the FPGA fabric to debug components on the CoreSight™ debug APB.

- `h2f_debug_apb`
- `h2f_debug_apb_sideband`
- `h2f_debug_apb_reset`
- `h2f_debug_apb_clock`

Peripheral Signal Interfaces

The DMA controller interface allows soft IP in the FPGA fabric to communicate with the DMA controller in the HPS. You can configure up to eight separate interface channels.

- `f2h_dma_req0`—FPGA DMA controller peripheral request interface 0
- `f2h_dma_re q1`—FPGA DMA controller peripheral request interface 1
- `f2h_dma_req2`—FPGA DMA controller peripheral request interface 2
- `f2h_dma_req3`—FPGA DMA controller peripheral request interface 3
- `f2h_dma_req4`—FPGA DMA controller peripheral request interface 4
- `f2h_dma_req5`—FPGA DMA controller peripheral request interface 5
- `f2h_dma_req6`—FPGA DMA controller peripheral request interface 6
- `f2h_dma_req7`—FPGA DMA controller peripheral request interface 7

Each of the DMA peripheral request interface contains the following three signals:

- `f2h_dma_req`—This signal is used to request burst transfer using the DMA
- `f2h_dma_single`—This signal is used to request single word transfer using the DMA
- `f2h_dma_ack`—This signal indicates the DMA acknowledgment upon requests from the FPGA

Related Information

DMA Controller on page 16-1
For details about the DMA Controller, refer to *DMA controller* chapter.

Other Interfaces

Related Information

Cortex-A9 MPCore on page 9-4
For more information, refer to *Cortex-A9 MPU Subsystem*.

MPU Standby and Event Interfaces

MPU standby and event signals are notification signals to the FPGA fabric that the MPU is in standby. Event signals are used to wake up the Cortex-A9 processors from a wait for event (WFE) state. The standby and event signals are included in the following interfaces:

- `h2f_mpu_events`—MPU standby and event interface, including the following signals.
- `h2f_mpu_eventi`—Sends an event from logic in the FPGA fabric to the MPU. This FPGA-to-HPS signal is used to wake up a processor that is in a Wait For Event state. Asserting this signal has the same effect as executing the `SEV` instruction in the Cortex-A9. This signal must be de-asserted until the FPGA fabric is powered-up and configured.
- `h2f_mpu_evento`—Sends an event from the MPU to logic in the FPGA fabric. This HPS-to-FPGA signal is asserted when an SEV instruction is executed by one of the Cortex-A9 processors.
- `h2f_mpu_standbywfe[1:0]`—Indicates whether each Cortex-A9 processor is in the WFE state
- `h2f_mpu_standbywfi[1:0]`—Indicates whether each Cortex-A9 processor is in the wait for interrupt (WFI) state
- `h2f_mpu_gp`—General purpose interface

The MPU provides signals to indicate when it is in a standby state. These signals are available to custom hardware designs in the FPGA fabric.

Related Information

Cortex-A9 MPCore on page 9-4
For more information, refer to *Cortex-A9 MPU Subsystem*.

FPGA-to-HPS Interrupts

You can configure the HPS component to provide 64 general-purpose FPGA-to-HPS interrupts, allowing soft IP in the FPGA fabric to trigger interrupts to the MPU's generic interrupt controller (GIC). The interrupts are implemented through the following 32-bit interfaces:

- `f2h_irq0`—FPGA-to-HPS interrupts 0 through 31
- `f2h_irq1`—FPGA-to-HPS interrupts 32 through 63

The FPGA-to-HPS interrupts are asynchronous on the FPGA interface. Inside the HPS, the interrupts are synchronized to the MPU's internal peripheral clock (`periphclk`).

Related Information

HPS Component Interfaces on page 28-1
There are various HPS peripherals to FPGA interrupt interfaces that you can configure. To learn the complete list of interfaces, refer to the *Instantiating the HPS Component* chapter.

Boot from FPGA Interface

You can enable the boot from FPGA interface to indicate the availability of preloader software in the FPGA memory. This interface is used to indicate the availability of a fallback preloader software in FPGA memory as well. The fallback preloader is used when there is no valid preloader image found in HPS flash memories.

Input-only General Purpose Interface

You can enable a general purpose interface that is connected to the general purpose I/O (GPIO) peripheral of the HPS. This is an input-only interface with 14-bit wide width. The interface share the same I/O pins with the HPS DDR SDRAM controller.

HPS Simulation Support 29

2014.06.30

cv_54030 Subscribe Send Feedback

This section describes the simulation support for the hard processor system (HPS) component. The HPS simulation models support interfaces between the HPS and FPGA fabric, including:

- Bus functional models (BFMs) for most interfaces between HPS and FPGA fabric
- A simulation model for the HPS SDRAM memory

The HPS simulation support does not include modules implemented in the HPS, such as the ARM Cortex-A9 MPCore processor.

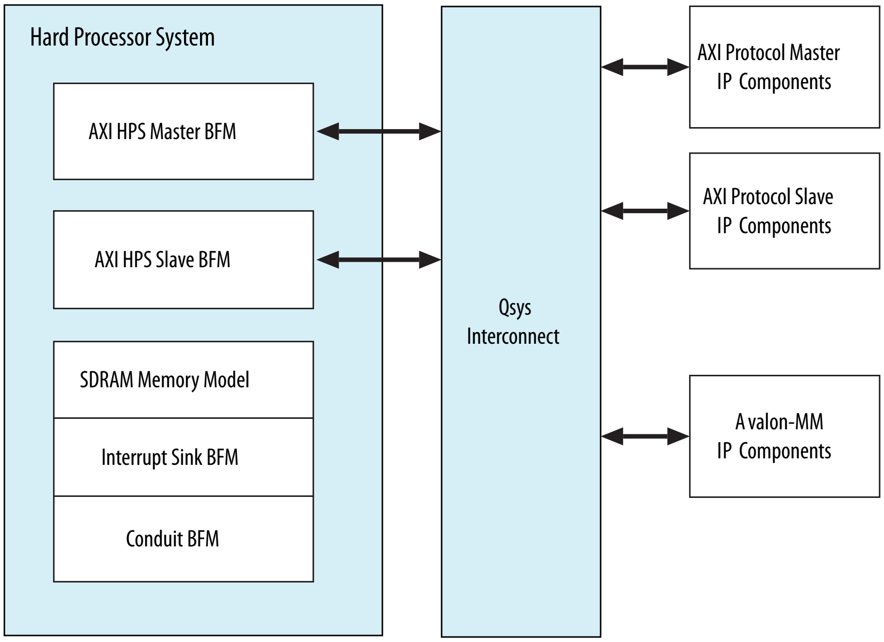
You specify simulation support files when you instantiate the HPS component in the Qsys system integration tool. When you enable a particular HPS-FPGA interface, Qsys provides the corresponding model during the generation process.

The HPS simulation support enables you to develop and verify your own FPGA soft logic or intellectual property (IP) that interfaces to the HPS component.

The simulation model supports the following interfaces:

- Clock and reset interfaces
- FPGA-to-HPS Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) slave interface
- HPS-to-FPGA AXI master interface
- Lightweight HPS-to-FPGA AXI master interface
- FPGA-to-HPS SDRAM interface
- Microprocessor unit (MPU) general-purpose I/O interface
- MPU standby and event interface
- Interrupts interface
- Direct memory access (DMA) controller peripheral request interface
- Debug Advanced Peripheral Bus (APB) interface
- System Trace Macrocell (STM) hardware event
- FPGA cross trigger interface
- FPGA trace port interface
- Boot from FPGA interface
- Input only general purpose interface

Figure 29-1: HPS BFM Block Diagram



The HPS BFMs use standard function calls from the Altera BFM application programming interface (API), as detailed in the remainder of this section.

HPS simulation supports only Verilog HDL or SystemVerilog simulation environments.

Clock and Reset Interfaces

Related Information

Memory-Mapped Interfaces on page 28-1

Clock Interface

Qsys generates the clock source BFM for each clock output interface from the HPS component. For HPS-to-FPGA user clocks, specify the BFM clock rate in the **User clock frequency field** in the **HPS Clocks** page when instantiating the HPS component in Qsys.

The HPS-to-FPGA trace port interface unit generates a clock output to the FPGA, named `h2f_tpiu_clock`. In simulation, the clock source BFM also represents this clock output's behavior.

Table 29-1: HPS Clock Output Interface Simulation Model

The Altera clock source BFM application programming interface (API) applies to all the BFMs listed in this table. Your Verilog interfaces use the same API, passing in different instance names.

Interface Name	BFM Instance Name
h2f_user0_clock	h2f_user0_clock_inst
h2f_user1_clock	h2f_user1_clock_inst
h2f_user2_clock	h2f_user2_clock_inst
h2f_tpiu_clock	h2f_tpiu_clock_inst

Qsys does not generate BFMs for FPGA-to-HPS clock input interfaces.

Reset Interface

The HPS reset request and handshake interfaces are connected to Altera conduit BFMs for simulation.

Table 29-2: HPS Reset Input Interface Simulation Model

You can monitor the reset request interface state changes or set the interface by using the API listed.

Interface Name	BFM Instance Name	API Function Names
f2h_cold_reset_req	f2h_cold_reset_req_inst	get_f2h_cold_rst_req_n()
f2h_debug_reset_req	f2h_debug_reset_req_inst	get_f2h_dbg_rst_req_n()
f2h_warm_reset_req	f2h_warm_reset_req_inst	get_f2h_warm_rst_req_n()

h2f_warm_reset_handshake	h2f_warm_reset_handshake_inst	set_h2f_pending_rst_req_n()
		get_f2h_pending_rst_ack_n()

Table 29-3: HPS Reset Output Interface Simulation Model

The Altera reset source BFM application programming interface applies to all the BFMs listed.

Interface Name	BFM Instance Name
h2f_reset	h2f_reset_inst
h2f_cold_reset	h2f_cold_reset_inst
h2f_debug_apb_reset	h2f_debug_apb_reset_inst

Table 29-4: Configuration of Reset Source BFM for HPS Reset Output Interface

The HPS reset output interface is connected to a reset source BFM. Qsys configures the BFM as shown. The parameter value of the instantiated BFM as configured for HPS simulation.

Parameter	BFM Value	Meaning
Assert reset high	Off	This parameter is off, specifying an active-low reset signal from the BFM.
Cycles of initial reset	0	This parameter is 0, specifying that the BFM does not assert the reset signal automatically.

FPGA-to-HPS AXI Slave Interface

The FPGA-to-HPS AXI slave interface, `f2h_axi_slave`, is connected to a Mentor Graphics AXI slave BFM for simulation with an instance name of `f2h_axi_slave_inst`. Qsys configures the BFM as shown in the following table. The BFM clock input is connected to `f2h_axi_clock` clock.

Table 29-5: Configuration of FPGA-to-HPS AXI Slave BFM

Parameter	Value
AXI Address Width	32
AXI Read Data Width	32, 64, 128
AXI Write Data Width	32, 64, 128
AXI ID Width	8

You control and monitor the AXI slave BFM by using the BFM API.

Related Information

- **Memory-Mapped Interfaces** on page 28-1
- **Mentor Verification IP Altera Edition User Guide**

HPS-to-FPGA AXI Master Interface

The HPS-to-FPGA AXI master interface, `h2f_axi_master`, is connected to a Mentor Graphics AXI master BFM for simulation with an instance name of `h2f_axi_master_inst`. Qsys configures the BFM as shown in the following table. The BFM clock input is connected to `h2f_axi_clock` clock.

Table 29-6: Configuration of HPS-to-FPGA AXI Master BFM

Parameter	Value
AXI Address Width	30

Parameter	Value
AXI Read and Write Data Width	32, 64, 128
AXI ID Width	12

You control and monitor the AXI master BFM by using the BFM API.

Related Information

- **Memory-Mapped Interfaces** on page 28-1
- **Mentor Verification IP Altera Edition User Guide**

Lightweight HPS-to-FPGA AXI Master Interface

The lightweight HPS-to-FPGA AXI master interface, `h2f_lw_axi_master`, is connected to a Mentor Graphics AXI master BFM for simulation with an instance name of `h2f_lw_axi_master_inst`. Qsys configures the BFM as shown in the following table. The BFM clock input is connected to `h2f_lw_axi_clock` clock.

Table 29-7: Configuration of Lightweight HPS-to-FPGA AXI Master BFM

Parameter	Value
AXI Address Width	21
AXI Read and Write Data Width	32
AXI ID Width	12

You control and monitor the AXI master BFM by using the BFM API.

Related Information

- **Memory-Mapped Interfaces** on page 28-1
- **Mentor Verification IP Altera Edition User Guide**

FPGA-to-HPS SDRAM Interface

The HPS component contains a memory interface simulation model to which all of the FPGA-to-HPS SDRAM interfaces are connected. The model is based on the HPS implementation and provides cycle-level accuracy, reflecting the true bandwidth and latency of the interface. However, the model does not have the detailed configuration provided by the HPS software, and hence does not reflect any inter-port scheduling that might occur under contention on the real hardware when different priorities or weights are used.

Functional Description—Hard Memory Interface

For more information, refer to "EMI-Related HPS Features in SoC Devices" in the *Functional Description —Hard Memory Interface* chapter in volume 3 of the *External Memory Interface Handbook*.

HPS-to-FPGA MPU General Purpose I/O Interface

The HPS-to-FPGA MPU general-purpose I/O interface is connected to an Altera conduit BFM for simulation. The following table lists the name of each interface, along with API function names for each type of simulation. You can monitor the interface state changes or set the interface by using the API listed.

Table 29-8: HPS-to-FPGA MPU General Purpose I/O Interface Simulation Model

Interface Name	BFM Instance Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names

h2f_mpu_gp	h2f_mpu_gp_inst	set_h2f_mpu_gp_out()
		get_h2f_mpu_gp_in()
			set_gp_out()
			get_gp_in()

HPS-to-FPGA MPU Event Interface

The HPS-to-FPGA MPU event interface is connected to an Altera conduit BFM for simulation. The following table lists the name of each interface, along with API function names for each type of simulation. You can monitor the interface state changes or set the interface by using the API listed.

Table 29-9: HPS-to-FPGA MPU Event Interface Simulation Model

The usage of conduit `get_*()` and `set_*()` API functions is the same as with the general Avalon conduit BFM.

Interface Name	BFM Instance Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names

h2f_mpu_events	h2f_mpu_events_inst	get_h2f_mpu_eventi()
		set_h2f_mpu_evento()
		set_h2f_mpu_standbywfe()
		set_h2f_mpu_standbywfi()
			get_eventi()
			set_evento()
			set_standbywfe()
			set_standbywfi()

FPGA-to-HPS Interrupts Interface

The FPGA-to-HPS interrupts interface is connected to an Altera Avalon interrupt sink BFM for simulation.

Table 29-10: FPGA-to-HPS Interrupts Interface Simulation Model

Interface Name	BFM Instance Name
f2h_irq0	f2h_irq0_inst
f2h_irq1	f2h_irq1_inst

Note: The simulation support for HPS peripherals to FPGA interfaces are not supported at the moment.

Related Information

Reset Interface on page 29-3
The Altera Avalon interrupt sink BFM API applies to all the BFMs listed in the HPS Reset Output Interface Simulation Model.

HPS-to-FPGA Debug APB Interface

The HPS-to-FPGA debug APB interface simulation is not supported at the moment. Updates on this subject will be provided in upcoming versions of this handbook.

Product Support
For more information, refer to the KDB solution on the Altera product support solution page.

FPGA-to-HPS System Trace Macrocell (STM) Hardware Event Interface

The FPGA-to-HPS STM hardware event interface is connected to an Altera conduit BFM for simulation. The following table lists the name of each interface, along with API function name for each type of simulation. You can monitor the interface state changes or set the interface by using the API functions listed.

Table 29-12: FPGA-to-HPS STM Hardware Event Interface Simulation Model

Interface Name	BFM Name	RTL Simulation API Function Name	Post-Fit Simulation API Function Name
f2h_stm_hw_events	f2h_stm_hw_events_inst	get_f2h_stm_hwevents()	get_stm_events()

HPS-to-FPGA Cross-Trigger Interface

The HPS-to-FPGA cross-trigger interface is connected to an Altera conduit BFM for simulation. The following table lists the name of each interface, along with API function names for each type of simulation. You can monitor the interface state changes or set the interface by using the API functions listed.

Table 29-13: HPS-to-FPGA Cross-Trigger Interface Simulation Model

Interface Name	BFM Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names

h2f_cti	h2f_cti_inst	get_h2f_cti_trig_in()
		set_h2f_cti_trig_in_ack()
		set_h2f_cti_trig_out()
		get_h2f_cti_trig_out_ack()
		set_h2f_cti_asicctl()
		get_h2f_cti_fpga_clk_en()
			get_trig_in()
			set_trig_inack()
			set_trig_out()
			get_trig_outack()
			set_asicctl()
			get_clk_en()

HPS-to-FPGA Trace Port Interface

The HPS-to-FPGA trace port interface is connected to an Altera conduit BFM for simulation. The following table lists the name of each interface, along with API function names for each type of simulation. You can monitor the interface state changes or set the interface by using the API functions listed.

Table 29-14: HPS-to-FPGA Trace Port Interface Simulation Model

Interface Name	BFM Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names

h2f_tpiu	h2f_tpiu_inst	get_h2f_tpiu_clk_ctl()
		set_h2f_tpiu_data()
			get_traceclk_ctl()
			set_trace_data()

FPGA-to-HPS DMA Handshake Interface

The FPGA-to-HPS DMA handshake interface is connected to an Altera conduit BFM for simulation. The following table lists the name for each interface, along with API function names for each type of simulation. You can monitor the interface state changes or set the interface by using the API listed.

Table 29-15: FPGA-to-HPS DMA Handshake Interface Simulation Model

The usage of conduit `get_*()` and `set_*()` API functions is the same as with the general Avalon conduit BFM.

Interface Name	BFM Instance Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names

f2h_dma_req0	f2h_dma_req0_inst	get_f2h_dma_req0_req()
		get_f2h_dma_req0_single()
		set_f2h_dma_req0_ack()
			get_channel0_req()
			get_channel0_single()
			set_channel0_xx_ack()

Interface Name	BFM Instance Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names

f2h_dma_req1	f2h_dma_req1_inst	get_f2h_dma_req1_req()
		get_f2h_dma_req1_single()
		set_f2h_dma_req1_ack()
			get_channel1_req()
			get_channel1_single()
			set_channel1_xx_ack()

f2h_dma_req2	f2h_dma_req2_inst	get_f2h_dma_req2_req()
		get_f2h_dma_req2_single()
		set_f2h_dma_req2_ack()
			get_channel2_req()
			get_channel2_single()
			set_channel2_xx_ack()

f2h_dma_req3	f2h_dma_req3_inst	get_f2h_dma_req3_req()
		get_f2h_dma_req3_single()
		set_f2h_dma_req3_ack()
			get_channel3_req()
			get_channel3_single()
			set_channel3_xx_ack()

f2h_dma_req4	f2h_dma_req4_inst	get_f2h_dma_req4_req()
		get_f2h_dma_req4_single()
		set_f2h_dma_req4_ack()
			get_channel4_req()
			get_channel4_single()
			set_channel4_xx_ack()

f2h_dma_req5	f2h_dma_req5_inst	get_f2h_dma_req5_req()
		get_f2h_dma_req5_single()
		set_f2h_dma_req5_ack()
			get_channel5_req()
			get_channel5_single()
			set_channel5_xx_ack()

f2h_dma_req6	f2h_dma_req6_inst	get_f2h_dma_req6_req()
		get_f2h_dma_req6_single()
		set_f2h_dma_req6_ack()
			get_channel6_req()
			get_channel6_single()
			set_channel6_xx_ack()

f2h_dma_req7	f2h_dma_req7_inst	get_f2h_dma_req7_req()
		get_f2h_dma_req7_single()
		set_f2h_dma_req7_ack()
			get_channel7_req()
			get_channel7_single()
			set_channel7_xx_ack()

Boot from FPGA Interface

The boot from FPGA interface is connected to an Altera conduit BFM for simulation. You can monitor the interface state changes or set the interface by using the API functions in the table below.

Table 29-16: Boot from FPGA Interface Simulation Model

Interface Name	BFM Name	RTL simulation API function names	Post-fit simulation API function names

f2h_boot_from_fpga	f2h_boot_from_fpga_inst	get_f2h_boot_from_fpga_ready()
		get_f2h_boot_from_fpga_on_failure()
			get_boot_fpga_ready()
			get_boot_from_fpga_on_failure()

General Purpose Input (GPI) Interface

The general purpose input interface is connected to an Altera conduit BFM for simulation. You can monitor the interface state changes or set the interface by using the API functions in the table below.

Table 29-17: General Purpose Input Interface Simulation Model

Interface Name	BFM Name	RTL simulation API function names

hps_io	hps_io_inst	get_hps_io_gpio_inst_HLGPI0()
		get_hps_io_gpio_inst_HLGPI1()
		get_hps_io_gpio_inst_HLGPI2()
		get_hps_io_gpio_inst_HLGPI3()
		get_hps_io_gpio_inst_HLGPI4()
		get_hps_io_gpio_inst_HLGPI5()
		get_hps_io_gpio_inst_HLGPI6()
		get_hps_io_gpio_inst_HLGPI7()
		get_hps_io_gpio_inst_HLGPI8()
		get_hps_io_gpio_inst_HLGPI9()
		get_hps_io_gpio_inst_HLGPI10()
		get_hps_io_gpio_inst_HLGPI11()
		get_hps_io_gpio_inst_HLGPI12()
		get_hps_io_gpio_inst_HLGPI13()

Simulation Flows

This section describes the simulation flows for an HPS-based design.

Altera provides both functional register transfer level (RTL) simulation and post-fitter gate-level simulation flows. The simulation flows involve the following major steps, which are based on Altera Complete Design Suite (ACDS 14.0):

1. **Specifying HPS Simulation Model in Qsys** on page 29-11
2. **Generating HPS Simulation Model in Qsys** on page 29-13
3. **Running the Simulation** on page 29-13

Related Information

Simulating Altera Designs

For general information about simulation, refer to the *Simulating Altera Designs* chapter in volume 3 of the *Quartus II Handbook*.

Specifying HPS Simulation Model in Qsys

The following steps outline how to set up the HPS component for simulation.

1. Add the HPS component from the Qsys Component Library.
2. Configure the component based on your application needs by selecting or deselecting the HPS-FPGA interfaces.
3. Connect the appropriate HPS interfaces to other components in the system. For example, connect the FPGA-to-HPS AXI slave interface to an AXI master interface in another component in the system.

When you create your component, make sure the conduit interfaces have the correct role names, widths and are opposite in direction to what is shown in the HPS conduit Interfaces table.

HPS Conduit Interfaces on page 29-11

Generating HPS Simulation Model in Qsys

The following steps outline how to generate the simulation model.

1. In Qsys, click **Generate HDL** under the Generate menu.
2. For RTL simulation, perform the following steps:

   - Set **Create simulation model** to **Verilog**.
   - Click **Generate**.

   Note: HPS simulation does not support the VHDL simulation environment.

   For post-fit simulation, perform the following steps:

   - Turn on the **Create HDL design files for synthesis** option.
   - Turn on the **Create block symbol file (.bsf)** option.
   - Click **Generate**.

Related Information

- **Instantiating the HPS Component** on page 27-1

  For information about the BFM API.

Running HPS Post-Fit Simulation

The section describes how you run HPS post-fit simulation. After successful Qsys generation, perform the following steps:

1. Add the Qsys-generated synthesis file set to your Quartus II project by performing the following steps:
   a. In the Quartus II software, click **Settings** in the Assignments menu.
   b. In the **Settings** *<your Qsys system name>* dialog box, on the **Files** tab, browse to *<your project directory>/<your Qsys system name>*/**synthesis/** and select *<your Qsys system name>*.**qip**.
   c. Click **OK**.
2. You can instantiate the Qsys system that contains HPS component as your Quartus II project top-level entity, if necessary.
3. Compile the design by clicking **Start Compilation** in the Processing menu.
4. Change the EDA Netlist Writer settings, if necessary, by performing the following steps:
   a. Click **Settings** in the Assignment menu.
   b. On the **Simulation** tab, under the **EDA Tool Settings** tab, you can specify the following EDA Netlist Writer settings:
      - **Tool name**—The name of the simulation tool
      - **Format for output netlist**
      - **Output directory**
   c. Click **OK**.
5. To create the post-fitter simulation model with Quartus II EDA Netlist Writer, in the Start menu, point to **Processing** and click **Start EDA Netlist Writer**.
6. Compile the necessary simulation files in your simulation tool.
7. Start simulation.

BFM API hierarchy Format

For post-fit simulation, you must call the BFM API in your test program with a specific hierarchy. The hierarchy format is:

```
<DUT>.\<HPS>|fpga_interfaces|<interface><space>.<BFM>.<API function>
```

Where:

- *<DUT>* is the instance name of the design under test that you instantiated in your test bench that consists of the HPS component.
- *<HPS>* is the HPS component instance name that you use in your Qsys system.
- *<interface>* is the instance name for a specific FPGA-to-HPS or HPS-to-FPGA interface. This name can be found in the **fpga_interfaces.sv** file located in *<project directory>*/*<Qsys design name>*/**synthesis/submodules**.
- *<space>*—You must insert one space character after the interface instance name.
- *<BFM>* is the BFM instance name. In *<ACDS install>*/**ip/altera/hps/postfitter_simulation**, identify the SystemVerilog file corresponding to the interface type that you are using. The SystemVerilog file contains the BFM instance name.

For example, a path for the Lightweight HPS-to-FPGA master interface hierarchy could be formed as follows:

```
top.dut.\my_hps_component|fpga_interface|hps2fpga_light_weight .h2f_lw_axi_master
```

Notice the space after "hps2fpga_light_weight". Omitting this space would cause simulation failure because the instance name "hps2fpga_light_weight ", including the space, is the name used in the post-fit simulation model generated by the Quartus® II software.

Document Revision History

Table 29-21: Document Revision History

Date	Version	Changes
June 2014	2014.06.30	• Updated the Simulation Flows section. • Updated the Generating HPS Simulation Model in Qsys section.
February 2014	2014.02.28	Added new sections: • Boot from FPGA Interface • General Purpose Input (GPI) Interface Updated content in sections: • Specifying HPS Simulation Model in Qsys • Running HPS RTL Simulation
December 2013	2013.12.30	Maintenance release
November 2012	1.1	• Added debug APB, STM hardware event, FPGA cross trigger, FPGA trace port interfaces. • Added support for post-fit simulation. • Updated some API function names. • Removed DMA peripheral clock.
June 2012	1.0	Initial release.
May 2012	0.1	Preliminary draft.

Booting and Configuration Introduction A

2014.06.30

cv_5400a Subscribe Send Feedback

This topic describes the booting of the hard processor system (HPS) and the configuration of the FPGA portion of the Altera system-on-a-chip (SoC) device.

The HPS boot starts when a processor is released from reset (for example, on power up) and executes code in the internal boot ROM at the reset exception address. The boot process ends when the code in the boot ROM jumps to the next stage of the boot software. This next stage of boot software is referred to as the preloader. The preloader can be customized and is typically stored external to the HPS in a nonvolatile flash-based memory.

The processor can boot from the following sources:

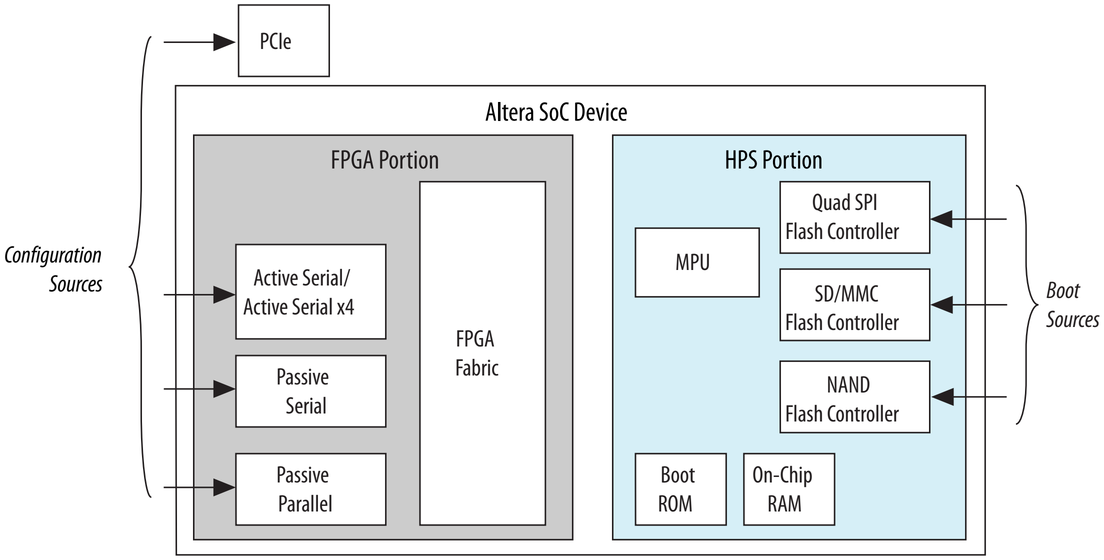
- NAND flash memory through the NAND flash controller
- Secure Digital/MultiMediaCard (SD/MMC) flash memory through the SD/MMC flash controller
- Serial peripheral interface (SPI) and quad SPI flash memory through the quad SPI flash controller using Slave Select 0
- FPGA fabric

The HPS boot supports indirect or direct execution of the preloader depending on the boot device. With indirect execution, the boot ROM code copies the preloader from the boot device into the on-chip RAM and jumps to it. Indirect execution is used for flash memory boot sources. With direct execution, the boot ROM code jumps to the preloader located in the FPGA fabric.

Configuration of the FPGA portion of the device starts when the FPGA portion is released from the reset state (for example, on power-on). The control block (CB) in the FPGA portion of the device is responsible for obtaining an FPGA configuration image and configuring the FPGA. The FPGA configuration ends when the configuration image has been fully loaded and the FPGA enters user mode. The FPGA configuration image is provided by users and is typically stored in non-volatile flash-based memory. The FPGA CB can obtain a configuration image from the HPS through the FPGA manager or from any of the sources supported by the Cyclone V FPGAs family.

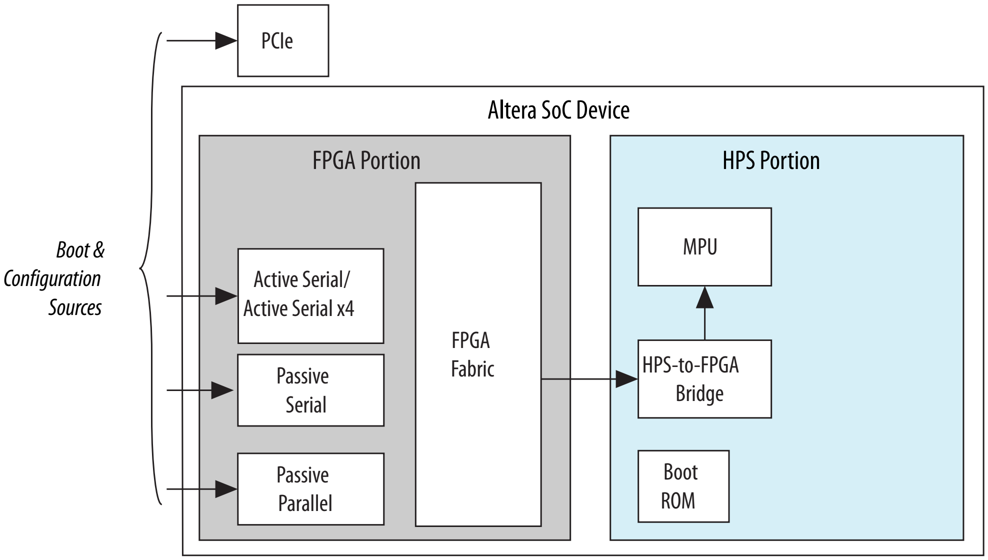
The following three figures illustrate the possible HPS boot and FPGA configuration schemes. The arrows in the figures denote the data flow direction. The following figure shows that the FPGA configuration and HPS boot occur independently. The FPGA configuration obtains its configuration image from a non-HPS source, while the HPS boot obtains its preloader from a non-FPGA fabric source.

Figure A-1: Independent FPGA Configuration and HPS Booting



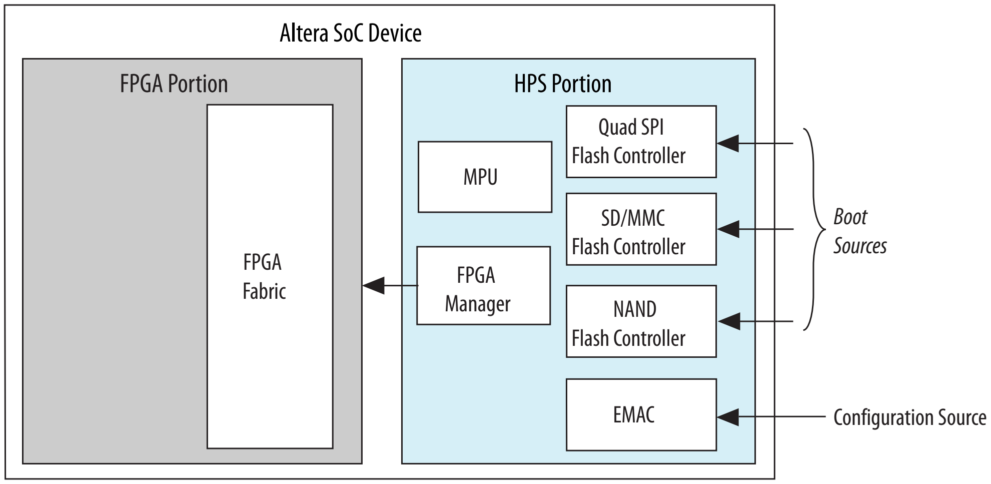
The following figure shows that the FPGA is first configured through one of its non-HPS configuration sources and then the HPS boots from the FPGA fabric. The HPS boot waits for the FPGA fabric to be powered on and in user mode before executing. The HPS boot ROM code executes the preloader from the FPGA fabric over the HPS-to-FPGA bridge. The preloader can be obtained from the FPGA RAM or by accessing an external interface, depending on your design and implementation.

Figure A-2: FPGA Configures First



The following figure shows that the HPS boots first through one of its non-FPGA fabric boot sources and then software running on the HPS configures the FPGA fabric through the HPS FPGA manager. The software on the HPS obtains the FPGA configuration image from any of its flash memory devices or communication interfaces, for example, the Ethernet media access controller (EMAC). The software is provided by users and the boot ROM is not involved in configuring the FPGA fabric.

Figure A-3: HPS Boots First



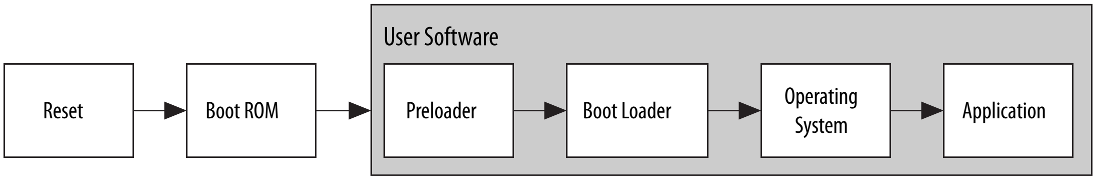
HPS Boot

Booting software on the HPS is a multi-stage process. Each stage is responsible for loading the next stage. The first software stage is the boot ROM. The boot ROM code locates and executes the second software stage, called the preloader. The preloader locates, and if present, executes the next software stage. The preloader and subsequent software stages (if present) are collectively referred to as user software.

Only the boot ROM code is located in the HPS. Subsequent software is located external to the HPS and is provided by users. The boot ROM code is only aware of the preloader and not aware of any potential subsequent software stages.

The figure below illustrates the typical boot flow. However, there may be more or less software stages in the user software than shown and the roles of the software stages may vary.

Figure A-4: Typical Boot Flow



Boot Process Overview

Reset

The boot process begins when a CPU in the MPU exits from the reset state. When a CPU exits from reset, it starts running code at the reset exception address. In normal operation, the boot ROM is mapped at the reset exception address so code starts running in the boot ROM.

It is possible to map the on-chip RAM or SDRAM at the reset exception address and run code other than the boot ROM code. However, this chapter assumes that the boot ROM maps to the reset exception address.

Boot ROM

The boot ROM contains software code that executes after a reset exits. If running on CPU0, the boot ROM code reads the boot select (BOOTSEL) and clock select (CLKSEL) values from the bsel and csel fields of the boot information register (boot info) in the system manager. This is done to determine the boot source and to set up the clock manager. The bsel and csel field values come from the BOOTSEL and CLKSEL pins which are sampled by the system manager coming out of reset.

The user software in CPU0 is responsible to release CPU1 from reset. If CPU1 is released from reset with the boot ROM mapped to the reset exception address, the boot ROM code jumps to the value in the CPU1 start address (`cpu1startaddr`) in the boot ROM code register group (`romcodegrp`) in the system manager.

BOOTSEL Field Values and Flash Device Selection

Table A-1: BOOTSEL Field Values and Flash Device Selection

BOOTSEL Field Value	Flash Device
0x0	Reserved
0x1	FPGA (HPS-to-FPGA bridge)
0x2	1.8 V NAND flash memory
0x3	3.3 V NAND flash memory
0x4	1.8 V SD/MMC flash memory with external transceiver
0x5	3.3 V SD/MMC flash memory with internal transceiver
0x6	1.8 V SPI or quad SPI flash memory
0x7	3.3 V SPI or quad SPI flash memory

Note:

If the BOOTSEL value is set 0x1 to Boot from FPGA, then the CLKSEL values are ignored. PLLs are bypassed so that OSC1 drives all the clocks.

For indirect execution from flash memory boot sources, the boot ROM code loads the preloader image from the flash device to the on-chip RAM and passes software control to the preloader in the on-chip RAM. For direct execution from the FPGA fabric boot source, the boot ROM code waits until the FPGA portion of the device is in user mode, and is ready to execute code and then passes software control to the preloader in the FPGA RAM.

Preloader

The function of the preloader is user-defined. However, typical functions include initializing the SDRAM interface and configuring the HPS I/O pins. Initializing the SDRAM allows the preloader to load the next stage of the boot software (that might not fit in the 60 kilobytes (KB) available in the on-chip RAM). A typical next software stage is the open source boot loader, U-boot.

The preloader is allowed to load the next boot software stage from any device available to the HPS. Typical sources include the same flash device that contains the preloader, a different flash device, or a communication interface such as an EMAC.

Boot Loader

The boot loader loads the operating system and passes software control to the operating system.

Boot ROM

The function of the boot ROM code is to determine the boot source, initialize the HPS after a reset, and jump to the preloader. In the case of indirect execution, the boot ROM code loads the preloader image from the flash memory to on-chip RAM. The boot ROM performs the following actions to initialize the HPS:

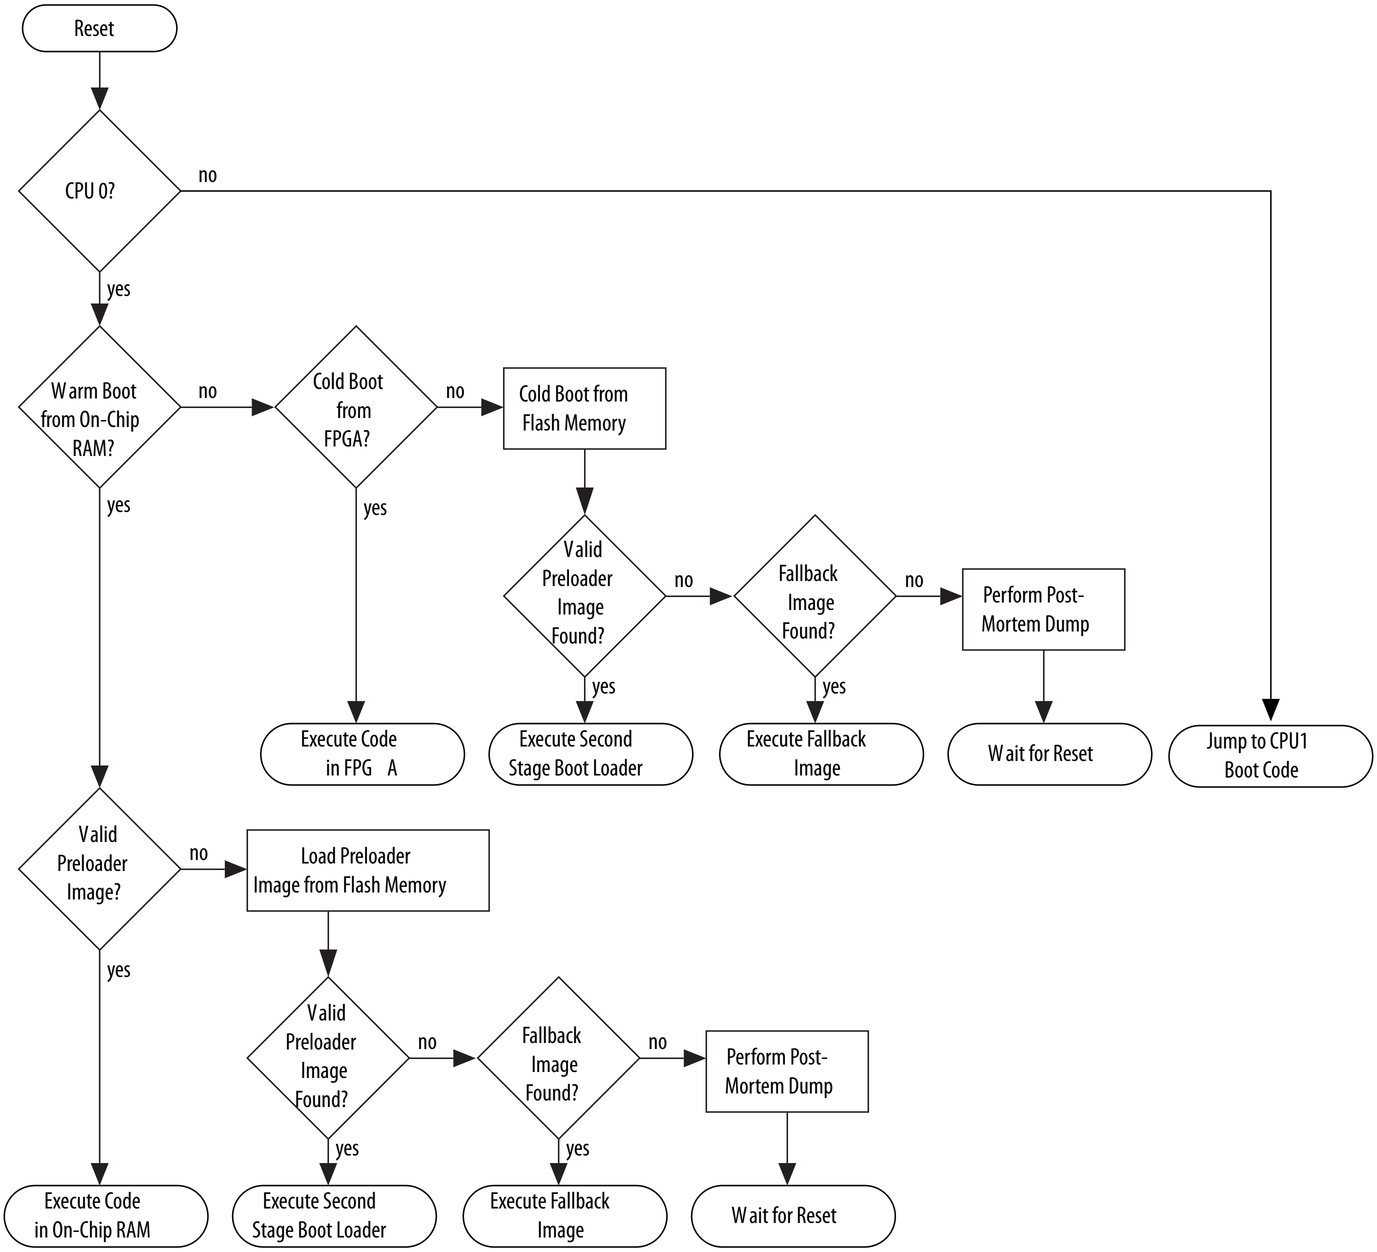
- Enable instruction cache, branch predictor, floating point unit, NEON vector unit
- Sets up the level 4 (l4) watchdog 0 timer
- Configures the main PLL and peripheral PLL based on the CLKSEL value
- Configures I/O elements and pin multiplexing based on the BOOTSEL value
- Initializes the flash controller to default settings

When booting from flash memory, the boot ROM code uses the top 4 KB of the on-chip RAM as data workspace. This area is reserved for the boot ROM code after a reset until the boot ROM code passes software control to preloader. This limits the maximum size of the preloader for indirect execution to 60 KB. For a warm boot or cold boot from FPGA, the boot ROM code does not reserve the top 4KB of the on-chip RAM, and the user may place user data in this area without being overwritten by boot ROM.

Boot ROM Flow

This section describes the software flow from reset until the boot ROM code passes software control to the preloader. The following figure illustrates that the boot ROM code can perform a warm boot from on-chip RAM, a cold boot from the FPGA portion of the device, or a cold boot from flash memory.

Figure A-5: BOOT ROM FLOW



During a cold boot from the FPGA portion of the device, the boot ROM code waits until the FPGA is ready and then attempts direct execution at address 0xC0000000 across the HPS-to-FPGA bridge. For example, the boot software could be provided by initialized on-chip RAM in the FPGA portion of the device at address 0xC0000000 (offset 0x0 from HPS-to-FPGA bridge). During a cold boot from flash memory, the boot ROM code attempts to load the first preloader image from flash memory to on-chip RAM and pass control to the preloader. If the image is invalid, the boot ROM code attempts to load up to three subsequent images from flash memory. If there is still no valid image found after the subsequent loads, the boot ROM code checks the FPGA portion of the device for a fallback image.

Warm boot from on-chip RAM has the highest priority to execute if the `warmramgrp` registers in the `romcodegrp` group in the system manager has been configured to support booting from on-chip RAM on a warm reset. When the enable in `warmramgrp` is enabled and length is set to 0x0, boot ROM will not perform CRC on the preloader image and immediately jump to the address in execution. If the length is not 0x0, boot ROM will ensure the preloader image passes the CRC check before the preloader image is executed.

If a valid preloader image cannot be found in the on-chip RAM, or the preloader in the on-chip RAM fails the CRC check, boot ROM code attempts to load the last valid preloader image loaded from the flash memory, identified by the `index` field of the initial software last image loaded register (`initswlastld`) in the `romcodegrp` group in the system manager. If the image is invalid, boot ROM code attempts to load up to three subsequent images from flash memory. If a valid preloader image cannot be found in the on-chip RAM or flash memory, the boot ROM code checks the FPGA portion of the device for a fallback image.

Loading the Preloader

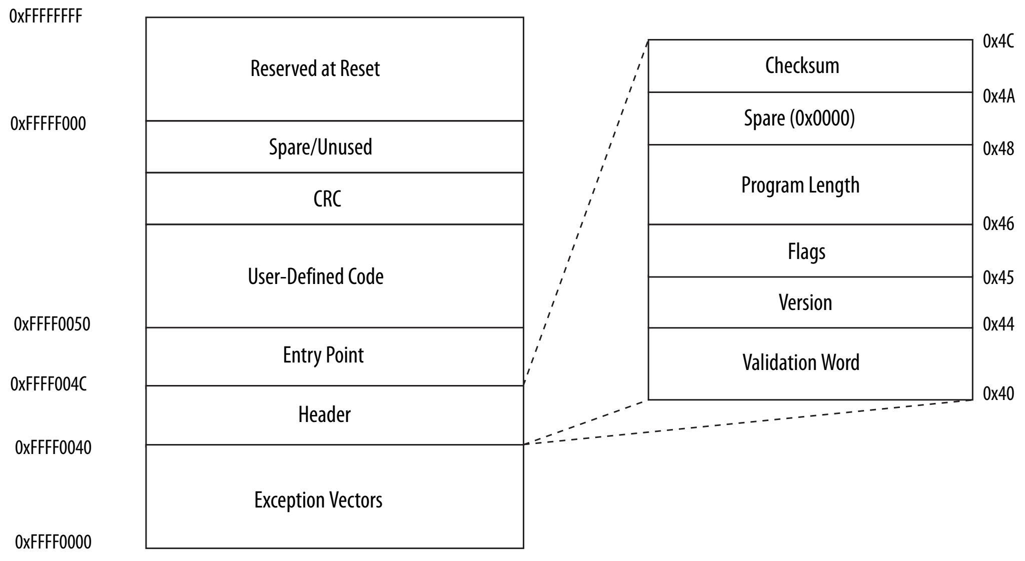
The boot ROM code loads the preloader image from flash memory into the on-chip RAM and passes control to the preloader. The boot ROM code checks for a valid image by verifying the header and cyclic redundancy check (CRC) in the preloader image.

The boot ROM code checks the header for the following information:

- Validation word—validates the preloader image. The validation word has a fixed value of 0x31305341.
- Version—indicates the header version.
- Program length—the total length of the image (in 32-bit words) from offset 0x0 to the end of code area, including exception vectors and CRC.
- Checksum—a checksum of all the bytes in the header, from offset 0x40 to 0x49.

The preloader image has a maximum size of 60 KB. This size is limited by the on-chip RAM size of 64 KB, where 4 KB is reserved as a workspace for the boot ROM data and stack. The preloader can use this 4 KB region (for its stack and data, for example) after the boot ROM code passes control to the preloader. This 4 KB region is overwritten by the boot ROM code on a subsequent reset. The following figure shows the preloader image layout in the on-chip RAM after being loaded from the boot ROM.

Figure A-6: Preloader Image Layout



Exception vectors—Exception vectors are located at the start of the on-chip RAM. Typically, the preloader remaps the lowest region of the memory map to the on-chip RAM (from the boot ROM) to create easier access to the exception vectors.

Header—contains information such as validation word, version, flags, program length, and checksum for the boot ROM code to validate the preloader image before passing control to the preloader.

Entry point—contains the preloader image address. After the boot ROM code validates the header, the boot ROM code jumps to this address.

User-defined code—typically contains the program code of the preloader.

CRC—contains a CRC of data from address 0xFFFF0000 to 0xFFFF0000+(Program Length*4)–0x0004. The polynomial used to validate the preloader image is *x 32 + x 26 + x 23 + x 22 + x 16 + x 12 + x 11 + x 10 + x 8 + x 7 + x 5 + x 4 + x 2 + x + 1*. There is no reflection of the bits. The initial value of the remainder is 0xFFFFFFFF and the final value is XORed with 0xFFFFFFFF.

Reserved at reset—the top 4 KB is reserved for the boot ROM code after a reset. The boot ROM code uses this area for internal structures, workspace, and post-mortem dump. This area includes the shared memory where the boot ROM code passes information to the preloader.

Shared Memory

The shared memory contains information that the boot ROM code passes to the preloader. The boot ROM code passes the location of shared memory to the preloader in register `r0`, as described in **HPS State on Entry to the Preloader** on page 30-11.

The shared memory contains the following information:

- Common—contains non-flash-specific settings used by the boot ROM code.
- Saved hardware register—contains hardware register values that the boot ROM code saves before the registers are modified by the boot ROM code.
- Flash device-specific—contains flash device-specific settings used by the boot ROM code that the preloader may use to continue using the flash device without reinitialization.

Table A-2: Shared Memory Block

Information Type	Content	Description
Common	Flash image	Indicates which preloader image (0-3) the boot ROM code loaded from the flash device. A nonzero value indicates that there was an error loading image 0 and the boot ROM code loaded another image.
	CLKSEL value used	Indicates the CLKSEL value used by the boot ROM code. Typically, this value is the value read from the `clksel` field of the `bootinfo` register in the system manager. However, if the PLL fails to lock, the boot ROM code ignores the `clksel` field and uses zero to indicate PLL bypass mode.
	BOOTSEL value used	Indicates the BOOTSEL value used by the boot ROM code. Typically, this value is the value read from the `bootsel` field of the `bootinfo` register in the system manager.
	Last page	Indicates the number of the last page read from the flash device.
	Page size	Indicates the page size (in bytes) used by the flash device. • For NAND flash memory, the boot ROM code reads this value from the NAND flash controller. • For SPI and quad SPI flash memory, the boot ROM code configures the page size through the quad SPI flash controller. • For SD/MMC flash memory, the boot ROM code configures the page size through the SD/MMC flash controller.
	Flash device type	Indicates the flash device used by the boot ROM code.
	Step complete	Track the completion state of up to 64 individual major steps during the boot process. The 64 bit value has one bit set for each major step completed in the boot

Information Type	Content	Description
Saved hardware registers	Status register (`stat`) of the reset manager	Contains reset source and event timeout information.
	Control (`ctrl`) register in the `romcodegrp` group in the system manager	Contains information used to control the boot ROM code.
	`initswstate` register in the `romcodegrp` group in the system manager	Contains the magic value 0x49535756 when the preloader has reached a valid state.
Flash device- specific (SD/MMC)	is_sd_card	Indicates the card type. 1 indicates SD card; 0 indicates MMC.
	is_sector_mode	Indicates the addressing mode of card. 1 indicates sector addressing mode; 0 indicates byte addressing mode.
	rca	Contains the relative card address, which is used for host-card communication during card identification
	partition_start_sector	Indicates the partition start offset in unit sectors. 0 indicates raw mode.
	partition_size	Size of the partition in unit sectors. 0 indicates raw mode.

Related Information

HPS State on Entry to the Preloader on page 30-11

L4 Watchdog 0 Timer

The L4 watchdog 0 timer is reserved for boot ROM use. While booting, if a watchdog reset happens before software control passes to the preloader, boot ROM code attempts to load the last valid preloader image, identified by the `initswlastld` register in the `romcodegrp` group in the system manager.

If the watchdog reset happens after the preloader has started executing but before the preloader writes a valid value to `initswstate` register, the boot ROM increments `initswlastld` and attempts to load that image. If the watchdog reset happens after the preloader writes a valid value to `initswstate` register, boot ROM code attempts to load the image indicated by `initswlastld` register.

HPS State on Entry to the Preloader

When the boot ROM code is ready to pass control to the preloader, the processor (CPU0) is in the following state:

- Instruction cache is enabled
- Branch predictor is enabled
- Data cache is disabled
- MMU is disabled
- Floating point unit is enabled
- NEON vector unit is enabled
- Processor is in ARM secure supervisor mode

The boot ROM code sets the ARM® Cortex™-A9 MPCore™ registers to the following values:

- r0—contains the pointer to the shared memory block, which is used to pass information from the boot ROM code to the preloader. The shared memory block is located in the top 4 KB of on-chip RAM.
- r1—contains the length of the shared memory.
- r2—unused and set to 0x0.
- r3—reserved.

All other MPCore registers are undefined.

Note: When booting CPU0 using the FPGA boot, or when booting CPU1 using any boot source, all MPCore registers, caches, the MMU, the floating point unit, and the NEON vector unit are undefined. HPS subsystems and the PLLs are undefined.

When the boot ROM code passes control to the preloader, the following conditions also exist:

- The boot ROM is still mapped to address 0x0.
- The L4 watchdog 0 timer is active and has been toggled.

Preloader

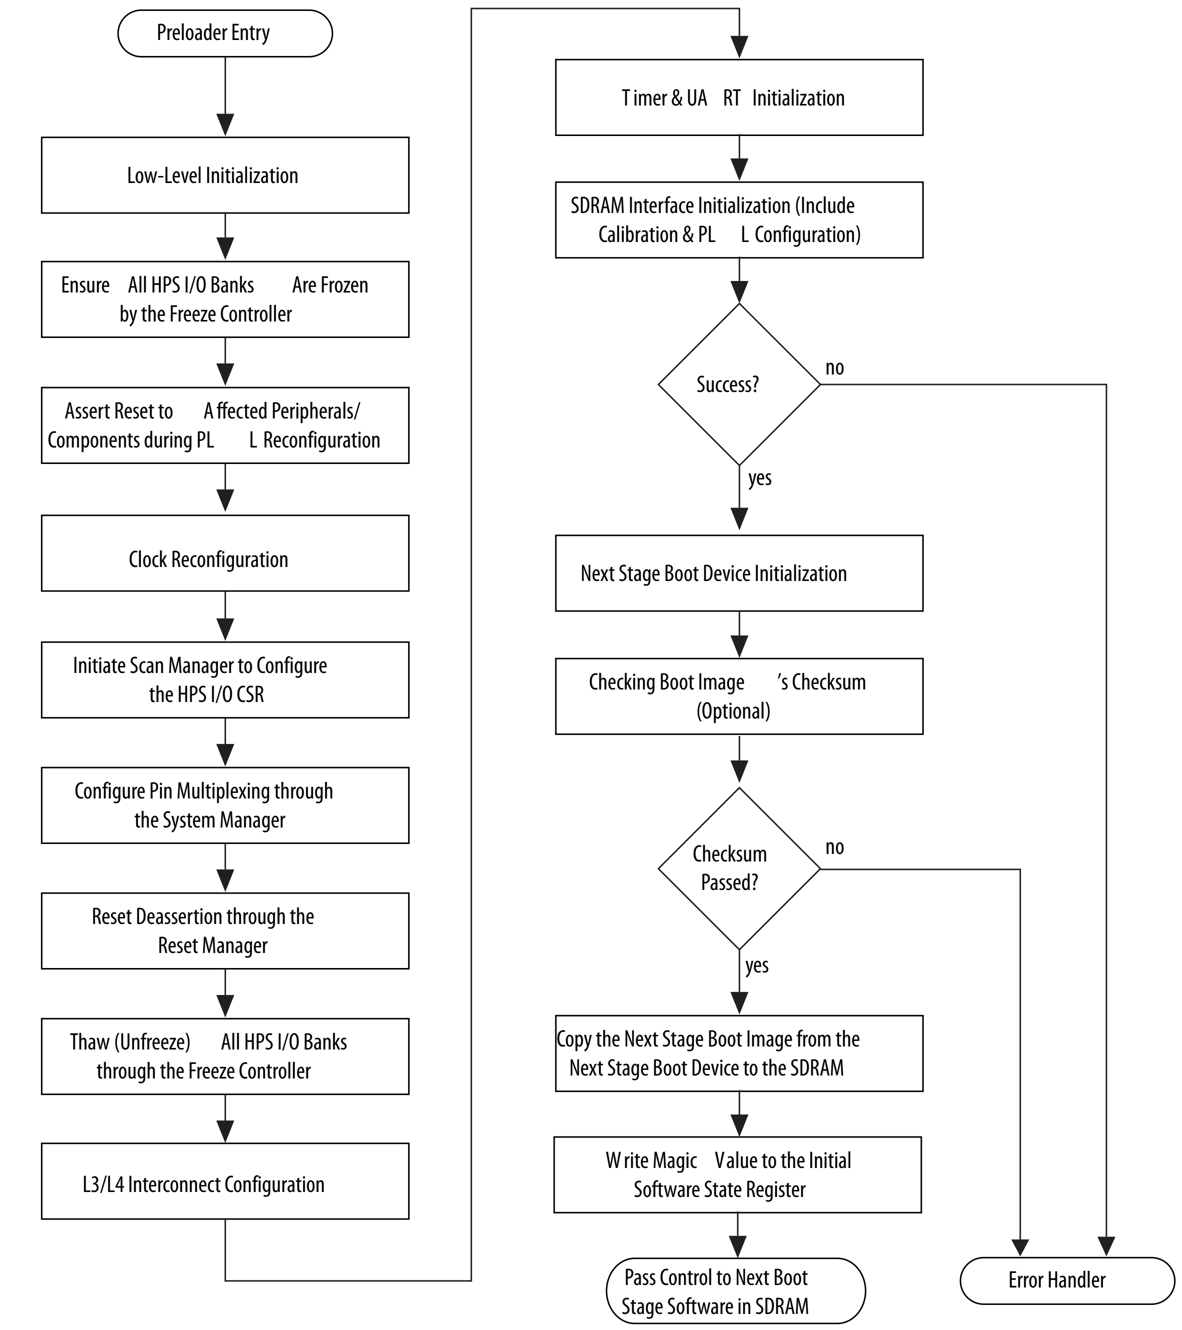
The preloader typically performs the following actions:

- Initialize the SDRAM interface.
- Configure the `remap` register to map the on-chip RAM to address 0x0 so that exceptions are handled by the preloader.
- The on-chip RAM is also accessible with the alias 0x0.
- Configure the HPS I/O through the scan manager.
- Configure pin multiplexing through the system manager.
- Configure HPS clocks through the clock manager.
- Initialize the flash controller (NAND, SD/MMC, or quad SPI) that contains the next stage boot software.
- Load the next stage boot software into the SDRAM and pass control to it.

Typical Preloader Boot Flow

This section describes a typical software flow from the preloader entry point until the software passes control to the next stage boot software.

Figure A-7: Typical Preloader Bootflow



Preloader Entry
Low-Level Initialization
Ensure All HPS I/O Banks Are Frozen by the Freeze Controller
Assert Reset to Affected Peripherals/ Components during PLL Reconfiguration
Clock Reconfiguration
Initiate Scan Manager to Configure the HPS I/O CSR
Configure Pin Multiplexing through the System Manager
Reset Deassertion through the Reset Manager
Thaw (Unfreeze) All HPS I/O Banks through the Freeze Controller
L3/L4 Interconnect Configuration
Timer & UART Initialization
SDRAM Interface Initialization (Include Calibration & PLL Configuration)
Success?
no
yes
Next Stage Boot Device Initialization
Checking Boot Image's Checksum (Optional)
Checksum Passed?
no
yes
Copy the Next Stage Boot Image from the Next Stage Boot Device to the SDRAM
Write Magic Value to the Initial Software State Register
Pass Control to Next Boot Stage Software in SDRAM
Error Handler

Low-level initialization steps include reconfiguring or disabling the L4 watchdog 0 timer, invalidating the instruction cache and branch predictor, remapping the on-chip RAM to the lowest memory region, and setting up the data area.

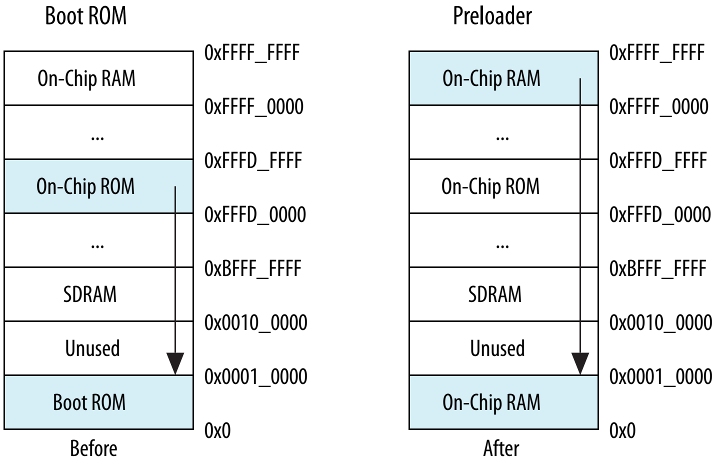
Upon entering the preloader, the L4 watchdog 0 timer is active. The preloader can either disable, reconfigure, or leave the watchdog timer unchanged. Once enabled after reset, the watchdog timer cannot be disabled, only paused.

The instruction cache and branch predictor, which were previously enabled by the boot ROM code, need to be invalidated.

The preloader needs to remap the exception vector table because the exception vectors are still pointing to the exception handler in the boot ROM when the preloader starts executing. By setting the L3 interconnect remap bit 0 to high, the on-chip RAM mirrors to the lowest region of the memory map. After this remap, the exception vectors will use the exception handlers in the preloader image.

The figure below shows the memory map before and after remap.

Figure A-8: Remapping the On-Chip RAM



The preloader can reconfigure all HPS clocks. During clock reconfiguration, the preloader asserts reset to the peripherals in the HPS affected by the clock changes.

The preloader configures HPS I/O pins through the scan manager and pin multiplexing through the system manager. The preloader initiates the freeze controller in the scan manager to freeze all the I/O pins and put them in a safe state during I/O configuration and pin multiplexing.

The I/O assignments for the HPS are configured as part of the IOCSR configuration in the preloader. Effectively, it's a bitstream that is sent to the device as part of the initialization code in the preloader.

The IOCSR is the complete bit settings for the I/Os embedded into the preloader code as a long array of configuration bits. There is an IOCSR for the EMIF portion of the HPS and for the other pins, they are physically separate bit streams. They are applied around the same time in the preloader. In the preloader code, you should be able to search for "IOCSR" and see a couple of long hex strings get manipulated.

The IOCSR in the preloader code is generated by the preloader generator from the **.hiof** file in the hps_isw_handoff folder. That file is generated when your design goes through the assembler, based on the usual **synthesis** > **filter** > **ASM** flow.

The SDRAM goes through full initialization for cold boot or a partial initialization for warm boot. For full initialization, the preloader configures the SDRAM PLL before releasing the SDRAM interface from reset. SDRAM calibration adjusts I/O delays and FIFO settings to compensate for any board skew or impairment in the board, FPGA portion of the device, or memory device. For partial initialization, SDRAM PLL configuration and SDRAM calibration is not necessary.

The preloader looks for a valid next stage boot image in the next stage boot device by checking the boot image validation data and checksum in the mirror image. Once validated, the preloader copies the next stage boot image from the next stage boot device to the SDRAM.

Before software passes control to the next stage boot software, the preloader can write a valid value (0x49535756) to the preloader `initswstate` register under the `romcodegrp` group in the system manager. This value indicates that there is a valid boot image in the on-chip RAM. When a warm reset occurs, the boot ROM code can check the `initswstate` register for the magic value to determine if it needs to reload the preloader image into the on-chip RAM.

Flash Memory Devices

The flash memory devices available for HPS boot are the NAND, SD/MMC, SPI, and quad SPI. The flash device can store the following kinds of files for booting purposes:

- Preloader binary file (up to four copies)
- Boot loader binary file
- Operating system binary file
- Application file
- FPGA programming files

Note: The preloader file must be stored in a partition with no file system.

NAND Flash Devices

The following figure shows that the preloader image is located at offsets which are multiples of the block size. For NAND device with block size equal or greater than 64kB, the preloader images are located in the first 4 blocks of the device. For NAND device with less than 64kB block size, preloader image needs to be placed in multiple of blocks. Since a block is the smallest area used for erase operation, any update to a particular image does not affect other images.

Figure A-9: NAND Flash Image Layout

NAND Flash Driver Features Supported in the Boot ROM Code

Table A-3: NAND Flash Support Features

Feature	Driver Support
Device	Open NAND Flash Interface (ONFI) 1.0 raw NAND or electronic signature devices, single layer cell (SLC)

Feature	Driver Support
Chip select	CS0 only. Only CS0 is available to the HPS, the other three chip selects are routed out to the FPGA portion of the device
Bus width	x8 only
Page size	512 bytes, 2 KB, 4 KB, or 8 KB
Page per block	32, 64, 128, 384 and 512
ECC	512-bytes with 8-bit correction

CLKSEL Pin Settings for the Quad SPI Controller

Table A-4: NAND Controller CLKSEL Pin Settings

Setting	CSEL Pin			
	0	1	2	3
osc1_clk (EOSC1 pin) range	10–50 MHz	10–12.5 MHz	12.5–25 MHz	25–50 MHz
Device frequency (nand_x_clk/25)	osc1_clk/25, 2 MHz max	osc1_clk*20/25, 9.6 MHz max	osc1_clk*10/25, 9.6 MHz max	osc1_clk*5/25, 9.6 MHz max
controller clock (nand_x_clk)	osc1_clk, 50 MHz max	osc1_clk*20, 240 MHz max	osc1_clk*10, 240 MHz max	osc1_clk*5, 240 MHz max
mpu_clk	osc1_clk, 50 MHz max	osc1_clk*32, 400 MHz max	osc1_clk*16, 400 MHz max	osc1_clk*8, 400 MHz max
PLL modes	Bypassed	Locked	Locked	Locked

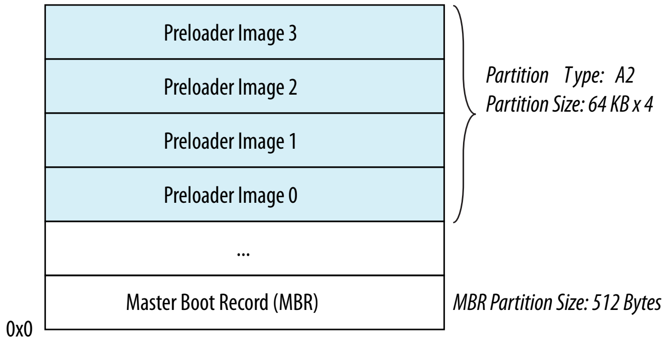
SD/MMC Flash Devices

The following figure shows the SD/MMC flash image layout. The master boot record (MBR) is located at the first 512 bytes of the memory. The MBR contains information of partitions (address and size of partition). The preloader image is always stored in partition A2. Partition A2 is a custom raw partition with no file system.

The start address of each image is based on the following formula:

Start address = partition start address + (<n> * 64 K), where <n> is the image number

Figure A-10: SD/MMC Flash Image Layout



The SD/MMC controller supports two booting modes:

- MBR (partition) mode
- The boot image is read from a custom partition (0xA2)
- The first image is located at the beginning of the partition, at offset 0x0
- Start address = partition start address
- Raw mode
- If the MBR signature is not found, SD/MMC driver assumes it is in raw mode.
- The boot image data is read directly from sectors in the user area and is located at the first sector of the SD/MMC.
- The first image is located at the start of the memory card, at offset 0
- Start address = 0

The MBR contains the partition table, which is always located on the first sector (LBA0) with a memory size of 512 bytes. The MBR consists of executable code, four partition entries, and the MBR signature. A MBR can be created by specific tools like the FDISK program.

Table A–5 lists the MBR structure.

Table A-5: MBR Structure

Offset	Size (Byte)	Description
0x000	446	Code area
0x1BE	16	Partition entry for partition 1
0x1CE	16	Partition entry for partition 2
0x1DE	16	Partition entry for partition 3
0x1EE	16	Partition entry for partition 4
0x1FE	2	MBR signature: 0xAA55

The standard MBR structure contains a partition with four 16-bytes entries. Thus, memory cards using this standard table cannot have more than four primary partitions or up to three primary partitions and one extended partition.

Each partition type is defined by the partition entry. The boot images are stored in a primary partition with custom partition type (0xA2). The SD/MMC flash driver does not support a file system, so the boot images are located in partition A2 at fixed locations.

Table A-6: Partition Entry

Offset	Size (Byte)	Description
0x0	1	Boot indicator. 0x80 indicates that is it bootable.
0x1	3	Starting CHS value
0x4	1	Partition type
0x5	3	Ending CHS value
0x8	4	LBA of first section in partition
0xB	4	Number of sectors in partition

The boot ROM code configures the SD/MMC controller to default settings for the supported SD/MMC flash memory.

Default settings of the SD/MMC controller.

Table A-7: SD/MMC Controller Default Settings

Parameter	Default	Register Value
Card type	1 bit	The card type register (`ctype`) in the SD/MMC controller registers (`sdmmc`) = 0x0
Timeout	Maximum	The timeout register (`tmout`) = 0xFFFFFFFF
FIFO threshold RX watermark level	1	The RX watermark level field (`rx_wmark`) of the FIFO threshold watermark register (`fifoth`) = 0x1

Parameter		Default	Register Value
Clock source		0	The clock source register (clksrc) = 0x0
Block size		512	The block size register (blksiz) = 0x200
Clock divider	Identification mode	32	The clock divider register (clkdiv)= 0x10 (2*16=32)
	Data transfer mode	Bypass	The clock divider register (clkdiv)= 0x00

CLKSEL Pin Settings for the SD/MMC Controller

Table A-8: SD/MMC Controller CLKSEL Pin Settings

Setting		CLKSEL Pin			
		0	1	2	3
osc1_clk (EOSC1 pin) range		10–50 MHz	10–12.5 MHz	12.5–25 MHz	25–50 MHz
ID mode	Device clock (sdmmc_cclk_out)	osc1_clk/128, 391 KHz max	osc1_clk/32, 391 KHz max	osc1_clk/64, 391 KHz max	osc1_clk/128, 391 KHz max
	Controller baud rate divisor	32	32	32	32
Data transfer mode	Device clock (sdmmc_cclk_out)	osc1_clk/4, 12.5 MHz max	osc1_clk*1, 12.5 MHz max	osc1_clk/2, 12.5 MHz max	osc1_clk/4, 12.5 MHz max
	Controller baud rate divisor (even numbers only)	1 (bypass)	1 (bypass)	1 (bypass)	1 (bypass)
Controller clock (sdmmc_clk)		osc1_clk, 50 MHz max	osc1_clk, 50 MHz max	osc1_clk, 50 MHz max	osc1_clk*2, 50 MHz max
mpu_clk		osc1_clk, 50 MHz max	osc1_clk*32, 400 MHz max	osc1_clk*16, 400 MHz max	osc1_clk*8, 400 MHz max
PLL modes		Bypassed	Locked	Locked	Locked

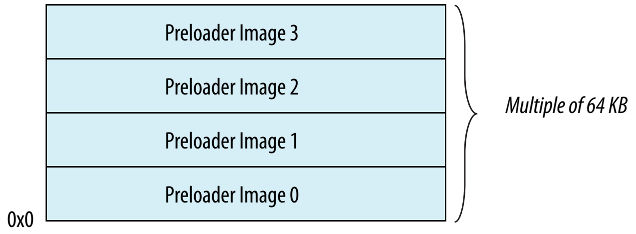
SPI and Quad SPI Flash Devices

The figure below shows the SPI and quad SPI flash image layout. The preloader image is always located at offsets which are multiples of 64 KB. The boot ROM code only supports QSPI devices with Mode Reset Command. Common manufacturers for Mode Reset Command are Spansion and Winbond.

The first image is located at offset 0 and followed by subsequent images. The start address of each image is based on the following formula:

Start address = (N * 64K), where N is the image number

Figure A-11: SPI and Quad SPI Flash Image Layout



The boot ROM code configures the quad SPI controller to default settings for the supported SPI or quad SPI flash memory.

Parameter	Default Setting	Register Value
SPI baud rate.	Divide by 4	The master mode baud rate divisor field (`bauddiv`) of the quad SPI configuration register (`cfg`) in the quad SPI controller registers (`qspiregs`) = 1.

Read opcode.	CLKSEL = 9 or 1: Normal read
	CLKSEL = 2 or 3: Fast read
		The read opcode in non-XIP mode field (`rdopcode`) in the device read instruction register (`devrd`) = 0x3 (for normal read) and 0xB (for fast read).

Instruction type.	Single I/O (1 bit wide)	The address transfer width field (`addrwidth`) and data transfer width field (`datawidth`) of the `devrd` register = 0.

Parameter	Default Setting	Register Value
Delay in master reference clocks for the length that the master mode chip select outputs are deasserted between words when the clock phase is zero.	200 ns	The clock delay for chip select deassert field (`nss`) in the quad SPI device delay register (`delay`). Refer to `delay[31:24]` in Table SPI and Quad SPI Flash Delay Configuration.
Delay in master reference clocks between one chip select being deactivated and the activation of another. This delay ensures a quiet period between the selection of two different slaves and requires the transmit FIFO to be empty.	0 ns	The clock delay for chip select deactivation field (`btwn`) in the `delay` register = 0x0.
Delay in master reference clocks between the last bit of the current transaction and the first bit of the next transaction. If the clock phase is zero, the first bit of the next transaction refers to the cycle in which the chip select is deselected.	20 ns	The clock delay for last transaction bit field (`after`) in the `delay` register. Refer to `delay[15:8]` in Table SPI and Quad SPI Flash Delay Configuration.
Added delay in master reference clocks between setting `qspi_n_ss_out` low and first bit transfer.	20 ns	The clock delay with `qspi_n_ss_out` field (`init`) in the `delay` register. Refer to `delay[7:0]` in Table SPI and Quad SPI Flash Delay Configuration.
Number of address bytes.	3 bytes	The number of address bytes field (`numaddrbytes`) of the device size register (`devsz`) = 2. Note: Before a reset, you must ensure that the QSPI flash device is configured to 3 bytes address mode for the boot ROM to function properly.

Quad SPI Controller CSEL Pin Settings

Table A-10: Quad SPI Controller CSEL Pin Settings

Setting	CSEL Pin			
	0[49]	1	2	3
`osc1_clk` (`EOSC1` pin) range	10–50 MHz	20–50 MHz	25–50 MHz	10–25 MHz

[49] Not applicable when on WARM reset.

Setting	CSEL Pin			
	0[49]	1	2	3
Device clock (sclk_out)	osc1_clk/4, 12.5 MHz max	osc1_clk/2, 25 MHz max	osc1_clk*1, 50 MHz max	osc1_clk*2, 50 MHz max
Controller clock (qspi_clk)	osc1_clk, 50 MHz max	osc1_clk*2, 100 MHz max	osc1_clk*4, 200 MHz max	osc1_clk*8, 200 MHz max
Controller baud rate divisor (even numbers only)	4	4	4	4
Flash read instruction (1 dummy byte for READ_FAST)	READ	READ	READ_FAST	READ_FAST
mpu_clk	osc1_clk, 50 MHz max	osc1_clk*8, 400 MHz max	osc1_clk*8, 400 MHz max	osc1_clk*16, 400 MHz max
PLL modes	Bypassed	Locked	Locked	Locked

SPI and Quad SPI Flash Delay Configuration

The delay register in the quad SPI controller registers (qspiregs) configures relative delay into the generation of the master output signals.

The SPI or quad SPI flash memory needs to meet the following timing requirements:

- T_{SLCH} (delay[7:0]): 20 ns
- T_{CHSH} (delay[15:8]): 20 ns
- T_{SHSL} (delay[31:24]): 200 ns

Table A-11: SPI and Quad SPI Flash Delay Configuration

CSEL Pin	T_{ref_clk} (ns)	T_{sclk_out} (ns)	Device Delay Register		
			delay[7:0]	delay[15:8]	delay[31:24]
0	20	80	1	1	6
1	10	40	2	2	16
2–3	5	20	4	4	36

The formula to calculate the delay is

delay[7:0] = T_{SLCH}/T_{qspi_clk}

delay[15:8] = T_{CHSH}/T_{qspi_clk}

delay[31:24] = $(T_{SHSL} - T_{sclk\_out})/T_{qspi\_clk}$

[49] Not applicable when on WARM reset.

FPGA Configuration

You can configure the FPGA portion of the SoC device with non-HPS sources or by utilizing the HPS. Software executing on the HPS configures the FPGA by writing the configuration image to the FPGA manager in the HPS. Software can control the configuration process and monitor the FPGA status by accessing the control and status register (CSR) interface in the FPGA manager.

Related Information

- **FPGA Manager** on page 4-1
  More information about configuring the FPGA through the HPS FPGA manager
- **http://www.altera.com/literature/hb/cyclone-v/cv_52007.pdf**
  For more information about configuring the FPGA in general, refer to the *Configuration, Design Security, and Remote System Upgrade* appendix in the Cyclone V Device Handbook, Volume 1.

Full Configuration

The HPS uses the FPGA manager to configure the FPGA portion of the device. The following sequence suggests one way for software to perform a full configuration:

- CONF_DONE = 1 and nSTATUS = 1 indicates successful configuration.
- CONF_DONE = 0 or nSTATUS = 0 indicates unsuccessful configuration. Complete steps 12 and 13, then go back and repeat steps 3 to 10 to reload the configuration image.

- If DCLK is unused, write a value of 4 to the DCLK count register (dclkcnt).
- If DCLK is used, write a value of 20,480 (0x5000) to the dclkcnt register.

If the HPS resets in the middle of a normal configuration data transfer before entering user mode, software can assume that the configuration is unsuccessful. After the HPS resets, software must repeat the steps for full configuration.

1. Set the cdratio and cfgwdth bits of the ctrl register in the FPGA manager registers (fpgamgrregs) to match the characteristics of the configuration image. These settings are dependant on the MSEL pins input.
2. Set the nce bit of the ctrl register to 0 to enable HPS configuration.
3. Set the en bit of the ctrl register to 1 to give the FPGA manager control of the configuration input signals.
4. Set the nconfigpull bit of the ctrl register to 1 to pull down the nCONFIG pin and put the FPGA portion of the device into the reset phase.
5. Poll the mode bit of the stat register and wait until the FPGA enters the reset phase.
6. Set the nconfigpull bit of the ctrl register to 0 to release the FPGA from reset.
7. Read the mode bit of the stat register and wait until the FPGA enters the configuration phase.
8. Clear the interrupt bit of nSTATUS (ns) in the gpio interrupt register (fpgamgr-regs.mon.gpio_porta_eoi).
9. Set the axicfgen bit of the ctrl register to 1 to enable sending configuration data to the FPGA.
10. Write the configuration image to the configuration data register (data) in the FPGA manager module configuration data registers (fpgamgrdata). You can also choose to use a DMA controller to transfer the configuration image from a peripheral device to the FPGA manager.
11. Use the fpgamgrregs.mon.gpio_ext_porta registers to monitor the CONF_DONE (cd) and nSTATUS (ns) bits.
12. Set the axicfgen bit of the ctrl register to 0 to disable configuration data on AXI slave.

13. Clear any previous DONE status by writing a 1 to the `dcntdone` bit of the DCLK status register (`dclkstat`) to clear the completed status flag.
14. Send the `DCLKs` required by the FPGA to enter the initialization phase.
15. Poll the `dcntdone` bit of the `DCLK` status register (`dclkstat`) until it changes to 1, which indicates that all the `DCLKs` have been sent.
16. Write a 1 to the `dcntdone` bit of the `DCLK` status register to clear the completed status flag.
17. Read the `mode` bit of the `stat` register to wait for the FPGA to enter user mode.
18. Set the `en` bit of the `ctrl` register to 0 to allow the external pins to drive the configuration input signals.

Document Revision History

Table A-12: Document Revision History

Date	Version	Changes
June 2014	2014.06.30	Maintenance release
February 2014	2014.02.28	Correction to "Leading the Preloader" section
December 2013	2013.12.30	• Updated figures in the Booting and Configuration Introduction section. • Updated the Rest and Boot ROM sections. • Updated the Shared Memory Block table. • Updated register names in the Full Configuration section.
November 2012	1.3	• Expanded shared memory block table. • Added CLKSEL tables. • Additional minor updates.
June 2012	1.2	Updated the HPS boot and FPGA configuration sections.

Date	Version	Changes
May 2012	1.1	• Updated the HPS boot section. • Added information about the flash devices used for HPS boot. • Added information about the FPGA configuration mode.
January 2012	1.0	Initial release.
