<tr><td>0</td><td>gb</td><td>This bit should read logic 0 before writing to Register 4 and Register 5. During a PHY or RevMII register access, the software sets this bit to 1'b1 to indicate that a Read or Write access is in progress. The Register 5 is invalid until this bit is cleared by the MAC. Therefore, Register 5 (GMII Data) should be kept valid until the MAC clears this bit during a PHY Write operation. Similarly for a read operation, the contents of Register 5 are not valid until this bit is cleared. The subsequent read or write operation should happen only after the previous operation is complete. Because there is no acknowledgment from the PHY to MAC after a read or write operation is completed, there is no change in the functionality of this bit even when the PHY is not present.<table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>Not Busy</td></tr><tr><td>0x1</td><td>Busy</td></tr></table></td><td>RW</td><td>0x0</td></tr>
</table>

GMII_Data

The GMII Data register stores Write data to be written to the PHY register located at the address specified in Register 4 (GMII Address Register). This register also stores the Read data from the PHY register located at the address specified by Register 4.

Module Instance	Base Address	Register Address

GMII_Data Fields

Bit	Name	Description	Access	Reset
15:0	gd	This field contains the 16-bit data value read from the PHY or RevMII after a Management Read operation or the 16-bit data value to be written to the PHY or RevMII before a Management Write operation.	RW	0x0

Flow_Control

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control block. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

Flow_Control Fields

Bit	Name	Description	Access	Reset
31:16	pt	This field holds the value to be used in the Pause Time field in the transmit control frame. Because the Pause Time bits are double-synchronized to the (G) MII clock domain, then consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.	RW	0x0
7	dzpq	When this bit is set, it disables the automatic generation of the Zero-Quanta Pause Control frames on the de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i/mti_flowctrl_i). When this bit is reset, normal operation with automatic Zero-Quanta Pause Control frame generation is enabled. **Value** **Description** 0x1 Disable Auto Gen. of Zero-Quanta Pause 0x0 Enable Auto Gen. of Zero-Quanta Pause	RW	0x0
5:4	plt	This field configures the threshold of the PAUSE timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of PAUSE Frame. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot-times), and PLT = 01, then a second PAUSE frame is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256 - 28) slot times after the first PAUSE frame is transmitted. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface. **Value** **Description** 0x0 Pause time - 4 slot times 0x1 Pause time - 28 slot times 0x2 Pause time - 144 slot times 0x3 Pause time - 256 slot times	RW	0x0

Bit	Name	Description	Access	Reset
3	`up`	When this bit is set, then in addition to the detecting Pause frames with the unique multicast address, the MAC detects the Pause frames with the station's unicast address specified in the MAC Address0 High Register and MAC Address0 Low Register. When this bit is reset, the MAC detects only a Pause frame with the unique multicast address specified in the 802.3x standard. **Value** — **Description** 0x0 — MAC Detects Pause MCA 0x1 — MAC Detects Pause MCA and UCA	`RW`	`0x0`
2	`rfe`	When this bit is set, the MAC decodes the received Pause frame and disables its transmitter for a specified (Pause) time. When this bit is reset, the decode function of the Pause frame is disabled. **Value** — **Description** 0x0 — Decode Func. of Pause Frame Disabled 0x1 — MAC decodes the received Pause	`RW`	`0x0`
1	`tfe`	In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames. In half-duplex mode, when this bit is set, the MAC enables the back-pressure operation. When this bit is reset, the back-pressure feature is disabled. **Value** — **Description** 0x0 — Transmit Flow Control Disable 0x1 — Transmit Flow Control Enable	`RW`	`0x0`

Bit	Name	Description	Access	Reset
0	fca_bpa	This bit initiates a Pause Control frame in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. In the full-duplex mode, this bit should be read as 1'b0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 1'b1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 1'b0. The Flow Control register should not be written to until this bit is cleared. In the half-duplex mode, when this bit is set (and TFE is set) , then backpressure is asserted by the MAC. During backpressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. **Value** / **Description** 0x0 — Pause Ctrl Frame and BPA off 0x1 — Init Pause Ctrl Frame and BPA	RW	0x0

VLAN_Tag

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. Because the VLAN Tag register is double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

vl RW 0x0															

VLAN_Tag Fields

Bit	Name	Description	Access	Reset
19	vthm	When set, the most significant four bits of the VLAN tag's CRC are used to index the content of Register 354 (VLAN Hash Table Register). A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table. When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison. When reset, the VLAN Hash Match operation is not performed.	RW	0x0
18	esvl	When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.	RW	0x0
17	vtim	When set, this bit enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The frames with matched VLAN Tag are marked as matched.	RW	0x0
16	etv	When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering. **Value** — **Description** 0x0 — Disable 12-Bit VLAN Tag Compare 0x1 — Enable 12-Bit VLAN Tag Compare	RW	0x0

Bit	Name	Description	Access	Reset
15:0	vl	This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field: * Bits [15:13]: User Priority * Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) * Bits[11:0]: VLAN tag's VLAN Identifier (VID) field When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 or 0x88a8 as VLAN frames.	RW	0x0

Version

The Version registers identifies the version of the EMAC. This register contains two bytes: one specified by Synopsys to identify the core release number, and the other specified by Altera.

Module Instance	Base Address	Register Address

LPI_Control_Status Fields

Bit	Name	Description	Access	Reset
19	lpitxa	This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the transmit side. This bit is not functional in the GMAC-CORE configuration in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding frames (in the core) and pending frames (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any frame for transmission or the application issues a TX FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If TX FIFO Flush is set, in Bit 20 of Register 6 (Operation Mode Register), when the MAC is in the LPI mode, the MAC exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. **Value** — **Description** 0x0 — LPI TX Automate Disabled 0x1 — LPI TX Automate Enabled	RW	0x0
18	plsen	This bit enables the link status received on the RGMII receive paths to be used for activating the LPI LS TIMER. When set, the MAC uses the link-status bits of Register 54 (SGMII/RGMII/SMII Status Register) and Bit 17 (PLS) for the LPI LS Timer trigger. When cleared, the MAC ignores the link-status bits of Register 54 and takes only the PLS bit. **Value** — **Description** 0x0 — MAC Ignores Link Status Bits 0x1 — MAC Uses Link Status Bits	RW	0x0
17	pls	This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (okay) at least for the time indicated by the LPI LS TIMER. When set, the link is considered to be okay (up) and when reset, the link is considered to be down. **Value** — **Description** 0x0 — Link Down 0x1 — Link Up (okay)	RW	0x0

Bit	Name	Description	Access	Reset
16	lpien	When set, this bit instructs the MAC Transmitter to enter the LPI state. When reset, this bit instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. **Value** **Description** 0x0 MAC Transmitter exit LPI State 0x1 MAC Transmitter enters LPI State	RW	0x0
9	rlpist	When set, this bit indicates that the MAC is receiving the LPI pattern on the GMII or MII interface. **Value** **Description** 0x0 MAC is not receiving LPI Pattern 0x1 MAC receiving LPI Pattern	RO	0x0
8	tlpist	When set, this bit indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface. **Value** **Description** 0x0 MAC Transmitting LPI Pattern 0x1 MAC Transmitting LPI Pattern	RO	0x0
3	rlpiex	When set, this bit indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register. Note: This bit may not get set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than 3 clock cycles of l3_sp_clk. **Value** **Description** 0x0 MAC RX receiving LPI Patterns 0x1 MAC RX Stopped receiving LPI Patterns	RO	0x0

Bit	Name	Description	Access	Reset
2	`rlpien`	When set, this bit indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register. Note: This bit may not get set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than 3 clock cycles of l3_sp_clk. **Value** **Description** 0x0 MAC Receiver Not In LPI State 0x1 MAC Receiver In LPI State	`RO`	`0x0`
1	`tlpiex`	When set, this bit indicates that the MAC transmitter has exited the LPI state after the user has cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register. **Value** **Description** 0x0 MAC Transmitter Non LPI State 0x1 MAC Transmitter Exited LPI State	`RO`	`0x0`
0	`tlpien`	When set, this bit indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register. **Value** **Description** 0x0 MAC Transmitter Not in LPI State 0x1 MAC Transmitter Entered LPI State	`RO`	`0x0`

LPI_Timers_Control

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Module Instance	Base Address	Register Address
`emac0`	`0xFF700000`	`0xFF700034`

Interrupt_Mask Fields

Bit	Name	Description	Access	Reset
10	`lpiim`	When set, this bit disables the assertion of the interrupt signal because of the setting of the LPI Interrupt Status bit in Register 14 (Interrupt Status Register). **Value** — **Description** 0x0 — LPI Interrupt Mask Disabled 0x1 — LPI Interrupt Mask Enabled	RW	0x0

Bit	Name	Description	Access	Reset
9	`tsim`	When set, this bit disables the assertion of the interrupt signal because of the setting of Timestamp Interrupt Status bit in Register 14 (Interrupt Status Register). **Value** **Description** 0x0 Timestamp Interrupt Mask Disabled 0x1 Timestamp Interrupt Mask Enabled	`RW`	`0x0`
2	`pcsancim`	When set, this bit disables the assertion of the interrupt signal because of the setting of PCS Auto-negotiation complete bit in Register 14 (Interrupt Status Register).	`RO`	`0x0`
1	`pcslchgim`	When set, this bit disables the assertion of the interrupt signal because of the setting of the PCS Link-status changed bit in Register 14 (Interrupt Status Register).	`RO`	`0x0`
0	`rgsmiiim`	When set, this bit disables the assertion of the interrupt signal because of the setting of the RGMII or SMII Interrupt Status bit in Register 14 (Interrupt Status Register). **Value** **Description** 0x0 RGMII or SMII Interrupt Mask Disable 0x1 RGMII or SMII Interrupt Mask Enable	`RW`	`0x0`

MAC_Address0_High

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. Because the MAC address registers are double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
`emac0`	`0xFF700000`	`0xFF700040`
`emac1`	`0xFF702000`	`0xFF702040`

Offset: `0x40`

Access: `RW`

MAC_Address9_High

The MAC Address9 High register holds the upper 16 bits of the 10th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address9 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
`emac0`	`0xFF700000`	`0xFF700088`

MAC_Address12_High Fields

Bit	Name	Description	Access	Reset
31	ae	When this bit is enabled, the address filter block uses the 13th MAC address for perfect filtering. When this bit is disabled, the address filter block ignores the address for filtering. **Value** **Description** 0x0 Second MAC address filtering disabled 0x1 Second MAC address filtering enabled	RW	0x0

Bit	Name	Description	Access	Reset
30	sa	When this bit is enabled, the MAC Address12[47:0] is used to compare with the SA fields of the received frame. When this bit is disabled, the MAC Address12[47:0] is used to compare with the DA fields of the received frame. **Value** **Description** 0x0 MAC address compare disabled 0x1 MAC address compare enabled	RW	0x0
29	mbc_5	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address12 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
28	mbc_4	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address12 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
27	mbc_3	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address12 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
26	mbc_2	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address12 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
25	mbc_1	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address12 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
24	`mbc_0`	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address12 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** — **Description** 0x0 — Byte is unmasked (i.e. is compared) 0x1 — Byte is masked (i.e. not compared)	RW	0x0
15:0	`addrhi`	This field contains the upper 16 bits (47:32) of the 13th 6-byte MAC address.	RW	0xFFFF

MAC_Address12_Low

The MAC Address12 Low register holds the lower 32 bits of the 13th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address
`emac0`	`0xFF700000`	`0xFF7000A4`
`emac1`	`0xFF702000`	`0xFF7020A4`

MAC_Address12_Low Fields

Bit	Name	Description	Access	Reset
31:0	`addrlo`	This field contains the lower 32 bits of the 13th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF

MAC_Address13_High

The MAC Address13 High register holds the upper 16 bits of the 14th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address13 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
`emac0`	`0xFF700000`	`0xFF7000A8`
`emac1`	`0xFF702000`	`0xFF7020A8`

MMC_Control

The MMC Control register establishes the operating mode of the management counters. Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

Module Instance	Base Address	Register Address

MMC_Control Fields

Bit	Name	Description	Access	Reset
8	ucdbc	When set, this bit enables MAC to update all the related MMC Counters for Broadcast frames dropped due to setting of DBF bit (Disable Broadcast Frames) of MAC Filter Register at offset 0x0004. When reset, MMC Counters are not updated for dropped Broadcast frames.	RW	0x0

Bit	Name	Description	Access	Reset
5	`cntprstlvl`	When low and bit 4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16). When this bit is high and bit 4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. **Value** **Description** 0x0 Preset All Counters to almost-half 0x1 Present All Counters almost-full	`RW`	`0x0`
4	`cntprst`	When this bit is set, all counters are initialized or preset to almost full or almost half according to bit 5. This bit is cleared automatically after 1 clock cycle. This bit, along with bit 5, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. **Value** **Description** 0x0 Counters not preset 0x1 Counters preset to full or almost full	`RW`	`0x0`
3	`cntfreez`	When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received frame. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. **Value** **Description** 0x0 Update MMC Counters 0x1 Freeze MMC counters to current value	`RW`	`0x0`

Bit	Name	Description	Access	Reset
2	`rstonrd`	When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read. **Value** **Description** 0x0 No reset after read 0x1 Reset after read	`RW`	`0x0`
1	`cntstopro`	When this bit is set, after reaching maximum value, the counter does not roll over to zero. **Value** **Description** 0x0 Counter Roll Over 0x1 Counter does not Roll Over	`RW`	`0x0`
0	`cntrst`	When this bit is set, all counters are reset. This bit is cleared automatically after one clock cycle. **Value** **Description** 0x0 Auto cleared after 1 clock cycle 0x1 All Counters Reset	`RW`	`0x0`

MMC_Receive_Interrupt

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Bit	Name	Description	Access	Reset
0	rxgbfrmis	This bit is set when the rxframecount_bg counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 Preset All Counters to almost-half 0x1 Present All Counters almost-full	RO	0x0

MMC_Transmit_Interrupt

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and the maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

15	`rx512t1023octgbfim`	Setting this bit masks the interrupt when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	`RW`	`0x0`
14	`rx256t511octgbfim`	Setting this bit masks the interrupt when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	`RW`	`0x0`

Bit	Name	Description	Access	Reset
13	rx128t255octgbfim	Setting this bit masks the interrupt when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
12	rx65t127octgbfim	Setting this bit masks the interrupt when the rx65to127octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
11	rx64octgbfim	Setting this bit masks the interrupt when the rx64octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
10	rxosizegfim	Setting this bit masks the interrupt when the rxoversize_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
9	rxusizegfim	Setting this bit masks the interrupt when the rxundersize_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
8	rxjaberfim	Setting this bit masks the interrupt when the rxjabbererror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
7	rxruntfim	Setting this bit masks the interrupt when the rxrunterror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
6	rxalgnerfim	Setting this bit masks the interrupt when the rxalignmenterror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
5	rxcrcerfim	Setting this bit masks the interrupt when the rxcrcerror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
4	rxmcgfim	Setting this bit masks the interrupt when the rxmulticastframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
3	rxbcgfim	Setting this bit masks the interrupt when the rxbroadcastframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
2	rxgoctim	Setting this bit masks the interrupt when the rxoctetcount_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
1	rxgboctim	Setting this bit masks the interrupt when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
0	rxgbfrmim	Setting this bit masks the interrupt when the rxframecount_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

MMC_Transmit_Interrupt_Mask

The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or maximum value. This register is 32-bits wide.

MMC_Transmit_Interrupt_Mask Fields

Bit	Name	Description	Access	Reset
25	txosizegfim	Setting this bit masks the interrupt when the txoversize_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
24	txvlangfim	Setting this bit masks the interrupt when the txvlanframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
23	txpausfim	Setting this bit masks the interrupt when the txpauseframes counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
22	`txexdeffim`	Setting this bit masks the interrupt when the txexcessdef counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	`RW`	`0x0`
21	`txgfrmim`	Setting this bit masks the interrupt when the txframecount_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	`RW`	`0x0`
20	`txgoctim`	Setting this bit masks the interrupt when the txoctetcount_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	`RW`	`0x0`
19	`txcarerfim`	Setting this bit masks the interrupt when the txcarriererror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	`RW`	`0x0`
18	`txexcolfim`	Setting this bit masks the interrupt when the txexcesscol counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	`RW`	`0x0`

Bit	Name	Description	Access	Reset
17	`txlatcolfim`	Setting this bit masks the interrupt when the txlatecol counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
16	`txdeffim`	Setting this bit masks the interrupt when the txdeferred counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
15	`txmcolgfim`	Setting this bit masks the interrupt when the txmulticol_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
14	`txscolgfim`	Setting this bit masks the interrupt when the txsinglecol_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
13	`txuflowerfim`	Setting this bit masks the interrupt when the txunderflowerror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
12	txbcgbfim	Setting this bit masks the interrupt when the txbroadcastframes_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
11	txmcgbfim	Setting this bit masks the interrupt when the txmulticastframes_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
10	txucgbfim	Setting this bit masks the interrupt when the txunicastframes_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
9	tx1024tmaxoctgbfim	Setting this bit masks the interrupt when the tx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
8	tx512t1023octgbfim	Setting this bit masks the interrupt when the tx512to1023octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
7	tx256t511octgbfim	Setting this bit masks the interrupt when the tx256to511octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
6	tx128t255octgbfim	Setting this bit masks the interrupt when the tx128to255octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
5	tx65t127octgbfim	Setting this bit masks the interrupt when the tx65to127octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
4	tx64octgbfim	Setting this bit masks the interrupt when the tx64octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
3	txmcgfim	Setting this bit masks the interrupt when the txmulticastframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
2	`txbcgfim`	Setting this bit masks the interrupt when the txbroadcastframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	`RW`	`0x0`
1	`txgbfrmim`	Setting this bit masks the interrupt when the txframecount_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	`RW`	`0x0`
0	`txgboctim`	Setting this bit masks the interrupt when the txoctetcount_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	`RW`	`0x0`

txoctetcount_gb

Number of bytes transmitted, exclusive of preamble and retried bytes, in good and bad frames

21	`rxipv6goim`	Setting this bit masks the interrupt when the rxipv6_gd_octets counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
20	`rxipv4udsbloim`	Setting this bit masks the interrupt when the rxipv4_udsbl_octets counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
19	`rxipv4fragoim`	Setting this bit masks the interrupt when the rxipv4_frag_octets counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
18	`rxipv4nopayoim`	Setting this bit masks the interrupt when the rxipv4_nopay_octets counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
17	`rxipv4heroim`	Setting this bit masks the interrupt when the rxipv4_hdrerr_octets counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
16	`rxipv4goim`	Setting this bit masks the interrupt when the rxipv4_gd_octets counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
13	`rxicmperfim`	Setting this bit masks the interrupt when the rxicmp_err_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
12	`rxicmpgfim`	Setting this bit masks the interrupt when the rxicmp_gd_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
11	`rxtcperfim`	Setting this bit masks the interrupt when the rxtcp_err_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
10	rxtcpgfim	Setting this bit masks the interrupt when the rxtcp_gd_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
9	rxudperfim	Setting this bit masks the interrupt when the rxudp_err_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
8	rxudpgfim	Setting this bit masks the interrupt when the rxudp_gd_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
7	rxipv6nopayfim	Setting this bit masks the interrupt when the rxipv6_nopay_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
6	rxipv6herfim	Setting this bit masks the interrupt when the rxipv6_hdrerr_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
5	rxipv6gfim	Setting this bit masks the interrupt when the rxipv6_gd_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
4	rxipv4udsblfim	Setting this bit masks the interrupt when the rxipv4_udsbl_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
3	rxipv4fragfim	Setting this bit masks the interrupt when the rxipv4_frag_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
2	rxipv4nopayfim	Setting this bit masks the interrupt when the rxipv4_nopay_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
1	rxipv4herfim	Setting this bit masks the interrupt when the rxipv4_hdrerr_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
0	rxipv4gfim	Setting this bit masks the interrupt when the rxipv4_gd_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

MMC_IPC_Receive_Interrupt

This register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

L3_L4_Control0 Fields

Bit	Name	Description	Access	Reset
21	l4dpim0	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 20 (L4DPM0) is set high.	RW	0x0
20	l4dpm0	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Destination Port number field for matching.	RW	0x0
19	l4spim0	When set, this bit indicates that the Layer 4 Source Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 18 (L4SPM0) is set high.	RW	0x0

Bit	Name	Description	Access	Reset
18	l4spm0	When set, this bit indicates that the Layer 4 Source Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Source Port number field for matching.	RW	0x0
16	l4pen0	When set, this bit indicates that the Source and Destination Port number fields for UDP frames are used for matching. When reset, this bit indicates that the Source and Destination Port number fields for TCP frames are used for matching. The Layer 4 matching is done only when either L4SPM0 or L4DPM0 bit is set high.	RW	0x0
15:11	l3hdbm0	IPv4 Frames: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: Bits [12:11] of this field correspond to Bits [6:5] of L3HSBM0, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 frames. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 127: All bits except MSb are masked. This field is valid and applicable only if L3DAM0 or L3SAM0 is set high.	RW	0x0
10:6	l3hsbm0	IPv4 Frames: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: This field contains Bits [4:0] of the field that indicates the number of higher bits of IP Source or Destination Address matched in the IPv6 frames. This field is valid and applicable only if L3DAM0 or L3SAM0 is set high.	RW	0x0
5	l3daim0	When set, this bit indicates that the Layer 3 IP Destination Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 4 (L3DAM0) is set high.	RW	0x0

Bit	Name	Description	Access	Reset
4	`l3dam0`	When set, this bit indicates that Layer 3 IP Destination Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When Bit 0 (L3PEN0) is set, you should set either this bit or Bit 2 (L3SAM0) because either IPv6 DA or SA can be checked for filtering.	RW	0x0
3	`l3saim0`	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 2 (L3SAM0) is set high.	RW	0x0
2	`l3sam0`	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When Bit 0 (L3PEN0) is set, you should set either this bit or Bit 4 (L3DAM0) because either IPv6 SA or DA can be checked for filtering.	RW	0x0
0	`l3pen0`	When set, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv6 frames. When reset, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv4 frames. The Layer 3 matching is done only when either L3SAM0 or L3DAM0 bit is set high.	RW	0x0

Layer4_Address0

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

L3_L4_Control1 Fields

Bit	Name	Description	Access	Reset
21	l4dpim1	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 20 (L4DPM1) is set high.	RW	0x0
20	l4dpm1	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Destination Port number field for matching.	RW	0x0
19	l4spim1	When set, this bit indicates that the Layer 4 Source Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 18 (L4SPM1) is set high.	RW	0x0

Bit	Name	Description	Access	Reset
18	l4spm1	When set, this bit indicates that the Layer 4 Source Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Source Port number field for matching.	RW	0x0
16	l4pen1	When set, this bit indicates that the Source and Destination Port number fields for UDP frames are used for matching. When reset, this bit indicates that the Source and Destination Port number fields for TCP frames are used for matching. The Layer 4 matching is done only when either L4SPM1 or L4DPM1 bit is set high.	RW	0x0
15:11	l3hdbm1	IPv4 Frames: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: Bits [12:11] of this field correspond to Bits [6:5] of L3HSBM1, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 frames. The following list describes the concatenated values of the L3HDBM1[1:0] and L3HSBM1 bits: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 127: All bits except MSb are masked. This field is valid and applicable only if L3DAM1 or L3SAM1 is set high.	RW	0x0
10:6	l3hsbm1	IPv4 Frames: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: This field contains Bits [4:0] of the field that indicates the number of higher bits of IP Source or Destination Address matched in the IPv6 frames. This field is valid and applicable only if L3DAM1 or L3SAM1 is set high.	RW	0x0
5	l3daim1	When set, this bit indicates that the Layer 3 IP Destination Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 4 (L3DAM1) is set high.	RW	0x0

Bit	Name	Description	Access	Reset
4	`l3dam1`	When set, this bit indicates that Layer 3 IP Destination Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When Bit 1 (L3PEN1) is set, you should set either this bit or Bit 2 (L3SAM1) because either IPv6 DA or SA can be checked for filtering.	`RW`	`0x0`
3	`l3saim1`	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 2 (L3SAM1) is set high.	`RW`	`0x0`
2	`l3sam1`	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When Bit 0 (L3PEN1) is set, you should set either this bit or Bit 4 (L3DAM1) because either IPv6 SA or DA can be checked for filtering.	`RW`	`0x0`
0	`l3pen1`	When set, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv6 frames. When reset, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv4 frames. The Layer 3 matching is done only when either L3SAM1 or L3DAM1 bit is set high.	`RW`	`0x0`

Layer4_Address1

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

When Bit 0 (L3PEN3) is reset in Register 292 (Layer 3 and Layer 4 Control Register 3), this register is not used.	RW	0x0

Hash_Table_Reg0

This register contains the first 32 bits of the hash table. The 256-bit Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming frame is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 8b'10111111 selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper 8 bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the Bit 1 (Pass All Multicast) is set in Register 1 (MAC Frame Filter), then all multicast frames are accepted regardless of the multicast hash values. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. Note: Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

vlt RW 0x0															

VLAN_Incl_Reg Fields

Bit	Name	Description	Access	Reset
19	csvl	When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted frames. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the transmitted frames.	RW	0x0
18	vlp	When this bit is set, the control Bits [17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used, and Bits [17:16] are ignored.	RW	0x0
17:16	vlc	* 2'b00: No VLAN tag deletion, insertion, or replacement * 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted frames with VLAN tags. * 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the frame after inserting the Type value (0x8100/0x88a8) in bytes 13 and 14. This operation is performed on all transmitted frames, irrespective of whether they already have a VLAN tag. * 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted frames (Bytes 13 and 14 are 0x8100/0x88a8). Note: Changes to this field take effect only on the start of a frame. If you write this register field when a frame is being transmitted, only the subsequent frame can use the updated value, that is, the current frame does not use the updated value.	RW	0x0
15:0	vlt	This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority, Bit 12 is the CFI/DEI, and Bits[11:0] are the VLAN tag's VID field.	RW	0x0

VLAN_Hash_Table_Reg

The 16-bit Hash table is used for group address filtering based on VLAN tag when Bit 18 (VTHM) of Register 7 (VLAN Tag Register) is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on Bit 16 (ETV) of VLAN Tag Register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper four bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written. Notes: * Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Timestamp_Control Fields

Bit	Name	Description	Access	Reset
25	atsen0	This field controls capturing the Auxiliary Snapshot Trigger 0. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored. **Value** **Description** 0x0 Auxiliary snapshot of event on ptp_aux_trig_i[0] input is disabled. 0x1 Auxiliary snapshot of event on ptp_aux_trig_i[0] input is enabled.	RW	0x0
24	atsfc	When set, it resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, auxiliary snapshots get stored in the FIFO. **Value** **Description** 0x0 Don't reset Auxiliary Snapshot FIFO pointers 0x1 Reset Auxiliary Snapshot FIFO pointers	RW	0x0
18	tsenmacaddr	When set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP frames when PTP is directly sent over Ethernet. **Value** **Description** 0x0 DA MAC address doesn't filter PTP frames 0x1 DA MAC address filters PTP frames	RW	0x0

Bit	Name	Description	Access	Reset
17:16	`snaptypsel`	These bits along with Bits 15 and 14 decide the set of PTP packet types for which snapshot needs to be taken.	RW	0x0
15	`tsmstrena`	When set, the snapshot is taken only for the messages relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. **Value** **Description** 0x0 Timestamp snapshot taken for messages relevant to slave node 0x1 Timestamp snapshot taken for messages relevant to master node	RW	0x0
14	`tsevntena`	When set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When reset, the snapshot is taken for all messages except Announce, Management, and Signaling. **Value** **Description** 0x0 Timestamp snapshot disabled for event messages 0x1 Timestamp snapshot only for event messages	RW	0x0
13	`tsipv4ena`	When set, the MAC receiver processes the PTP packets encapsulated in UDP over IPv4 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv4 packets. This bit is set by default. **Value** **Description** 0x0 Don't process PTP packets in UDP over IPv4 0x1 Process PTP packets in UDP over IPv4	RW	0x1
12	`tsipv6ena`	When set, the MAC receiver processes PTP packets encapsulated in UDP over IPv6 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv6 packets. **Value** **Description** 0x0 Don't process PTP packets in UDP over IPv6 0x1 Process PTP packets in UDP over IPv6	RW	0x0

Bit	Name	Description	Access	Reset
11	`tsipena`	When set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet frames. When this bit is clear, the MAC ignores the PTP over Ethernet packets. **Value** — **Description** 0x0 — Don't process PTP packets in Ethernet frames 0x1 — Process PTP packets in Ethernet frames	RW	0x0
10	`tsver2ena`	When set, the PTP packets are processed using the 1588 version 2 format. Otherwise, the PTP packets are processed using the version 1 format. **Value** — **Description** 0x0 — PTP packets processed with 1588 version 1 format 0x1 — PTP packets processed with 1588 version 2 format	RW	0x0
9	`tsctrlssr`	When set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment has to be programmed correctly depending on the PTP reference clock frequency and the value of this bit. **Value** — **Description** 0x0 — Timestamp Low register rolls over at 0x7FFF_FFFF 0x1 — Timestamp Low register rolls over at 1ns	RW	0x0
8	`tsenall`	When set, the timestamp snapshot is enabled for all frames received by the MAC. **Value** — **Description** 0x0 — Timestamp snapshot disabled 0x1 — Timestamp snapshot enabled	RW	0x0

Bit	Name	Description	Access	Reset
5	tsaddreg	When set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This is cleared when the update is completed. This register bit should be zero before setting it. **Value** **Description** 0x0 Timestamp Addend register is not updated 0x1 Timestamp Addend register is updated	RW	0x0
4	tstrig	When set, the timestamp interrupt is generated when the System Time becomes greater than the value written in the Target Time register. This bit is reset after the generation of the Timestamp Trigger Interrupt. **Value** **Description** 0x0 Timestamp not generated 0x1 Timestamp generated	RW	0x0
3	tsupdt	When set, the system time is updated (added or subtracted) with the value specified in Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the update is completed in hardware. The Timestamp Higher Word register is not updated. **Value** **Description** 0x0 Timestamp not updated (added or subtracted) with values in Register 452 and Register 453 0x1 Timestamp updated (added or subtracted) with values in Register 452 and Register 453	RW	0x0

Bit	Name	Description	Access	Reset
2	`tsinit`	When set, the system time is initialized (overwritten) with the value specified in the Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the initialization is complete. The Timestamp Higher Word register can only be initialized. **Value** — **Description** 0x0 — Timestamp not initialized (overwritten) by values in Register 452 and Register 453 0x1 — Timestamp initialized (overwritten) by values in Register 452 and Register 453	`RW`	`0x0`
1	`tscfupdt`	When set, this bit indicates that the system times update should be done using the fine update method. When reset, it indicates the system timestamp update should be done using the Coarse method. **Value** — **Description** 0x0 — Timestamp Coarse 0x1 — Timestamp Fine	`RW`	`0x0`
0	`tsena`	When set, the timestamp is added for the transmit and receive frames. When disabled, timestamp is not added for the transmit and receive frames and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the receive side, the MAC processes the 1588 frames only if this bit is set. **Value** — **Description** 0x0 — Timestamp not added 0x1 — Timestamp added for transmit and receive	`RW`	`0x0`

Sub_Second_Increment

In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

Module Instance	Base Address	Register Address
`emac0`	`0xFF700000`	`0xFF700704`
`emac1`	`0xFF702000`	`0xFF702704`

Offset: 0x704

Sub_Second_Increment Fields

Bit	Name	Description	Access	Reset
7:0	ssinc	The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time-Nanoseconds register has an accuracy of 1 ns (TSCTRLSSR bit is set). When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, you should program a value of 43 (0x2B) that is derived by 20ns/0.465.	RW	0x0

System_Time_Seconds

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to l3_sp_clk).

Target_Time_Nanoseconds Fields

Bit	Name	Description	Access	Reset
31	trgtbusy	The MAC sets this bit when the PPSCMD field (Bits[3:0]) in Register 459 (PPS Control Register) is programmed to 010 or 011. Programming the PPSCMD field to 010 or 011, instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. This bit is reserved when the Enable Flexible Pulse-Per-Second Output feature is not selected.	RO	0x0
30:0	ttslo	This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the both Target Timestamp registers, then based on the TRGTMODSEL0 field (Bits [6:5]) in Register 459 (PPS Control Register), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 0x3B9A_C9FF when TSCTRLSSR is set in the Timestamp control register. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.	RW	0x0

Timestamp_Status Fields

Bit	Name	Description	Access	Reset
29:25	atsns	This field indicates the number of Snapshots available in the FIFO. A value of 16 (equal to the depth of the FIFO) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set.	RO	0x0
24	atsstm	This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO. **Value** **Description** 0x0 Not Active 0x1 Aux timestamp snapshot full	RO	0x0
19:16	atsstn	These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of Auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list: * Bit 16: Auxiliary trigger 0 * Bit 17: Auxiliary trigger 1 * Bit 18: Auxiliary trigger 2 * Bit 19: Auxiliary trigger 3 The software can read this register to find the triggers that are set when the timestamp is taken.	RO	0x0
3	tstrgterr	This bit is set when the target time, being programmed in Target Time Registers, is already elapsed. This bit is cleared when read by the application. **Value** **Description** 0x0 When Read resets 0x1 Target Time Elapsed -Reg455 and Reg456	RO	0x0
2	auxtstrig	This bit is set high when the auxiliary snapshot is written to the FIFO. **Value** **Description** 0x0 System Time 0x1 System Time is >= Reg455 and Reg456	RO	0x0

Bit	Name	Description	Access	Reset
1	`tstargt`	When set, this bit indicates that the value of system time is greater or equal to the value specified in the Register 455 (Target Time Seconds Register) and Register 456 (Target Time Nanoseconds Register). **Value** — **Description** 0x0 — System Time 0x1 — System Time is >= Reg455 and Reg456	RO	0x0
0	`tssovf`	When set, this bit indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. **Value** — **Description** 0x0 — No Overflow 0x1 — Seconds Overflow	RO	0x0

PPS_Control Fields

Bit	Name	Description	Access	Reset
6:5	trgtmodsel0	This field indicates the Target Time registers (register 455 and 456) mode for PPS0 output signal **Value** / **Description** 0x0 Target Time regs generate interrupt event. 0x2 Target Time gen. interr event and sig pps0 0x3 Target Time No inter just start and stop sig pps0	RW	0x0
4	ppsen0	When set low, Bits[3:0] function as PPSCTRL (backward compatible). When set high, Bits[3:0] function as PPSCMD. **Value** / **Description** 0x0 Bits[3:0] function as ppsctrl0 0x1 Bits[3:0] function as ppscmd	RW	0x0

Bit	Name	Description	Access	Reset
3:0	`ppsctrl_ppscmd`	PPSCTRL0: PPS0 Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: -0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. -0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. -0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. -0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. -... -1111: The binary rollover is 32.768 KHz, and the digital rollover is 16.384 KHz. Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: * When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms * When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of: - One clock of 50 percent duty cycle and 537 ms period - Second clock of 463 ms period (268 ms low and 195 ms high) * When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of: - Three clocks of 50 percent duty cycle and 268 ms period - Fourth clock of 195 ms period (134 ms low and 61 ms high) This behavior is because of the non-linear toggling of bits in the digital rollover mode in Register 451 (System Time - Nanoseconds Register). Flexible PPS0 Output (ptp_pps_o[0]) Control Programming these bits with a non-zero value instructs the MAC to initiate an event. Once the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The Software should ensure that these bits are programmed only when they are all-zero. The following list describes the values of PPSCMD0: * 0000: No Command * 0001: START Single Pulse This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register. * 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. * 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. * 0100: STOP Pulse train at time This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. * 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train	RW	0x0

Auxiliary_Timestamp_Nanoseconds

This register, along with Register 461 (Auxiliary Timestamp Seconds Register), gives the 64-bit timestamp stored as auxiliary snapshot. The two registers together form the read port of a 64-bit wide FIFO with a depth of 16. Multiple snapshots can be stored in this FIFO. The ATSNS bits in the Timestamp Status register indicate the fill-level of this FIFO. The top of the FIFO is removed only when the last byte of Register 461 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read. In big-endian mode, it corresponds to the reading of Bits[7:0] of Register 461 (Auxiliary Timestamp - Seconds Register).

`ppswidth` `RW 0x0`															

PPS0_Width Fields

Bit	Name	Description	Access	Reset
31:0	`ppswidth`	These bits store the width between the rising edge and corresponding falling edge of the PPS0 signal output in terms of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20ns), and desired width between the rising and corresponding falling edges of PPS0 signal output is 80ns (that is, four units of sub-second increment value), then you should program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in Register 472 (PPS0 Interval Register).	`RW`	`0x0`

MAC_Address16_High

The MAC Address16 High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address16 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address18_High

The MAC Address18 High register holds the upper 16 bits of the 19th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address18 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address22_High

The MAC Address22 High register holds the upper 16 bits of the 23th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address22 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address26_High

The MAC Address26 High register holds the upper 16 bits of the 27th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address26 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address34_High

The MAC Address34 High register holds the upper 16 bits of the 35th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address34 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address38_High

The MAC Address38 High register holds the upper 16 bits of the 39th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address38 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF7008B0

MAC_Address50_High

The MAC Address50 High register holds the upper 16 bits of the 51th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address50 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address54_High

The MAC Address54 High register holds the upper 16 bits of the 55th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address54 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address58_High

The MAC Address58 High register holds the upper 16 bits of the 59th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address58 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address62_High

The MAC Address62 High register holds the upper 16 bits of the 63th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address62 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address66_High

The MAC Address66 High register holds the upper 16 bits of the 67th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address66 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address74_High

The MAC Address74 High register holds the upper 16 bits of the 75th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address74 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address78_High

The MAC Address78 High register holds the upper 16 bits of the 79th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address78 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset
25	`mbc_1`	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address81 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** — **Description** 0x0 — Byte is unmasked (i.e. is compared) 0x1 — Byte is masked (i.e. not compared)	`RW`	`0x0`
24	`mbc_0`	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address81 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** — **Description** 0x0 — Byte is unmasked (i.e. is compared) 0x1 — Byte is masked (i.e. not compared)	`RW`	`0x0`
15:0	`addrhi`	This field contains the upper 16 bits (47:32) of the 82th 6-byte MAC address.	`RW`	`0xFFFF`

MAC_Address81_Low

The MAC Address81 Low register holds the lower 32 bits of the 82th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address
`emac0`	`0xFF700000`	`0xFF700A0C`
`emac1`	`0xFF702000`	`0xFF702A0C`

Offset: `0xA0C`

MAC_Address82_High

The MAC Address82 High register holds the upper 16 bits of the 83th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address82 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address86_High

The MAC Address86 High register holds the upper 16 bits of the 87th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address86 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address90_High

The MAC Address90 High register holds the upper 16 bits of the 91th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address90 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address94_High

The MAC Address94 High register holds the upper 16 bits of the 95th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address94 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address98_High

The MAC Address98 High register holds the upper 16 bits of the 99th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address98 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700A90

MAC_Address102_High

The MAC Address102 High register holds the upper 16 bits of the 103th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address102 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address106_High

The MAC Address106 High register holds the upper 16 bits of the 107th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address106 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address110_High

The MAC Address110 High register holds the upper 16 bits of the 111th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address110 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address114_High

The MAC Address114 High register holds the upper 16 bits of the 115th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address114 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address118_High

The MAC Address118 High register holds the upper 16 bits of the 119th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address118 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address122_High

The MAC Address122 High register holds the upper 16 bits of the 123th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address122 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** — **Description** 0x0 — Byte is unmasked (i.e. is compared) 0x1 — Byte is masked (i.e. not compared)	`RW`	`0x0`
24	`mbc_0`	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address125 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** — **Description** 0x0 — Byte is unmasked (i.e. is compared) 0x1 — Byte is masked (i.e. not compared)	`RW`	`0x0`
15:0	`addrhi`	This field contains the upper 16 bits (47:32) of the 126th 6-byte MAC address.	`RW`	`0xFFFF`

MAC_Address125_Low

The MAC Address125 Low register holds the lower 32 bits of the 126th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address
`emac0`	`0xFF700000`	`0xFF700B6C`
`emac1`	`0xFF702000`	`0xFF702B6C`

Offset: `0xB6C`

MAC_Address126_High

The MAC Address126 High register holds the upper 16 bits of the 127th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address126 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

DMA Register Group Register Descriptions

DMA Register Group

Offset: 0x1000

Bus_Mode on page 17-808
The Bus Mode register establishes the bus operating modes for the DMA.

Transmit_Poll_Demand on page 17-812
The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

Receive_Poll_Demand on page 17-813
The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

Receive_Descriptor_List_Address on page 17-813
The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Transmit_Descriptor_List_Address on page 17-814
The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Status on page 17-815
The Status register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

Operation_Mode on page 17-820
The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization.

Interrupt_Enable on page 17-826
The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Missed_Frame_And_Buffer_Overflow_Counter on page 17-830
The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Receive_Interrupt_Watchdog_Timer on page 17-831
This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of Register 5 (Status Register)

AXI_Bus_Mode on page 17-832
The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

AHB_or_AXI_Status on page 17-835
This register provides the active status of the AXI interface's read and write channels. This register is useful for debugging purposes. In addition, this register is valid only in the Channel 0 DMA when multiple channels are present in the AV mode.

Current_Host_Transmit_Descriptor on page 17-836
The Current Host Transmit Descriptor register points to the start address of the current Transmit Descriptor read by the DMA.

Current_Host_Receive_Descriptor on page 17-836
The Current Host Receive Descriptor register points to the start address of the current Receive Descriptor read by the DMA.

Current_Host_Transmit_Buffer_Address on page 17-837
The Current Host Transmit Buffer Address register points to the current Transmit Buffer Address being read by the DMA.

Current_Host_Receive_Buffer_Address on page 17-837
The Current Host Receive Buffer Address register points to the current Receive Buffer address being read by the DMA.

HW_Feature on page 17-838
This register indicates the presence of the optional features or functions of the gmac. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bus_Mode

The Bus Mode register establishes the bus operating modes for the DMA.

Module Instance	Base Address	Register Address

Bus_Mode Fields

Bit	Name	Description	Access	Reset
25	aal	When this bit is set high and the FB bit is equal to 1, the AHB or AXI interface generates all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffer's start address) is not aligned, but subsequent bursts are aligned to the address. **Value** **Description** 0x0 No Address-Aligned Beats 0x1 Address-Aligned Beats (dependent on FB)	RW	0x0

Bit	Name	Description	Access	Reset
24	eightxpbl	When set high, this bit multiplies the programmed PBL value (Bits[22:17] and Bits[13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. **Value** **Description** 0x0 Non Multiply Mode 0x1 Multiplies PBL value by 8	RW	0x0
23	usp	When set high, this bit configures the Rx DMA to use the value configured in Bits[22:17] as PBL. The PBL value in Bits[13:8] is applicable only to the Tx DMA operations. When reset to low, the PBL value in Bits[13:8] is applicable for both DMA engines. **Value** **Description** 0x0 Configures TX RX DMA to PBL 0x1 Configures TX DMA to PBL	RW	0x0
22:17	rpbl	This field indicates the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read or Write. The Rx DMA always attempts to burst as specified in the RPBL bit each time it starts a Burst transfer on the host bus. You can program RPBL with values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. This field is valid and applicable only when USP is set high. **Value** **Description** 0x1 Beats Trans. in one Rx DMA Transaction 0x2 Beats Trans. in one Rx DMA Transaction 0x4 Beats Trans. in one Rx DMA Transaction 0x8 Beats Trans. in one Rx DMA Transaction 0x10 Beats Trans. in one Rx DMA Transaction 0x20 Beats Trans. in one Rx DMA Transaction	RW	0x1

Bit	Name	Description	Access	Reset
16	`fb`	This bit controls whether the AXI Master interface performs fixed burst transfers or not. When set, the AXI interface uses FIXED bursts during the start of the normal burst transfers. When reset, the AXI interface uses SINGLE and INCR burst transfer operations. For more information, see Bit 0 (UNDEFINED) of the AXI Bus Mode register. **Value** — **Description** 0x0 — SINGLE or INCR Burst 0x1 — FIXED Burst (1, 4, 8, or 16)	RW	0x0
13:8	`pbl`	These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable only for Tx DMA transactions. If the number of beats to be transferred is more than 32, then perform the following steps: 1. Set the 8xPBL mode. 2. Set the PBL. For example, if the maximum number of beats to be transferred is 64, then first set 8xPBL to 1 and then set PBL to 8. The PBL values have the following limitation: The maximum number of possible beats (PBL) is limited by the size of the Tx FIFO and Rx FIFO in the MTL layer and the data bus width on the DMA. The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO, except when specified.	RW	0x1

Bit	Name	Description	Access	Reset
7	`atds`	When set, the size of the alternate descriptor increases to 32 bytes (8 DWORDS). This is required when the Advanced Timestamp feature or the IPC Full Offload Engine (Type 2) is enabled in the receiver. The enhanced descriptor is not required if the Advanced Timestamp and IPC Full Checksum Offload (Type 2) features are not enabled. In such cases, you can use the 16 bytes descriptor to save 4 bytes of memory. When reset, the descriptor size reverts back to 4 DWORDs (16 bytes). This bit preserves the backward compatibility for the descriptor size. In versions prior to 3.50a, the descriptor size is 16 bytes for both normal and enhanced descriptor. In version 3.50a, descriptor size is increased to 32 bytes because of the Advanced Timestamp and IPC Full Checksum Offload Engine (Type 2) features. **Value** — **Description** 0x0 — MAC DMA Controller Clears Logic 0x1 — MAC DMA Controller Resets Logic	`RW`	`0x0`
6:2	`dsl`	This bit specifies the number of Word, Dword, or Lword (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When the DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA in Ring mode.	`RW`	`0x0`

Bit	Name	Description	Access	Reset
0	swr	When this bit is set, the MAC DMA Controller resets the logic and all internal registers of the MAC. It is cleared automatically after the reset operation has completed in all of the EMAC clock domains. Before reprogramming any register of the EMAC, you should read a zero (0) value in this bit . Note: * The Software reset function is driven only by this bit. Bit 0 of Register 64 (Channel 1 Bus Mode Register) or Register 128 (Channel 2 Bus Mode Register) has no impact on the Software reset function. * The reset operation is completed only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for the software reset completion. **Value** **Description** 0x0 MAC DMA Controller Clears Logic 0x1 MAC DMA Controller Resets Logic	RW	0x1

Transmit_Poll_Demand

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

Module Instance	Base Address	Register Address

Transmit_Poll_Demand Fields

Bit	Name	Description	Access	Reset
31:0	tpd	When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 18 (Current Host Transmit Descriptor Register). If that descriptor is not available (owned by the Host), the transmission returns to the Suspend state and the Bit 2 (TU) of Register 5 (Status Register) is asserted. If the descriptor is available, the transmission resumes.	RW	0x0

Receive_Poll_Demand

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

Receive_Poll_Demand Fields

Bit	Name	Description	Access	Reset
31:0	rpd	When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 19 (Current Host Receive Descriptor Register). If that descriptor is not available (owned by the Host), the reception returns to the Suspended state and the Bit 7 (RU) of Register 5 (Status Register) is not asserted. If the descriptor is available, the Rx DMA returns to the active state.	RW	0x0

Receive_Descriptor_List_Address

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Receive_Descriptor_List_Address Fields

Bit	Name	Description	Access	Reset
31:2	rdesla_32bit	This field contains the base address of the first descriptor in the Receive Descriptor list. The LSB bits (1:0) are ignored (32-bit wide bus) and internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).	RW	0x0

Transmit_Descriptor_List_Address

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

31:2	tdesla_32bit	This field contains the base address of the first descriptor in the Transmit Descriptor list. The LSB bits (1:0) are ignored (32-bit wide bus) and are internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).	RW	0x0

Status

The Status register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

Status Fields

Bit	Name	Description	Access	Reset
30	`glpii`	This bit indicates an interrupt event in the LPI logic of the EMAC. To reset this bit to 1'b0, the software must read the corresponding registers in the EMAC to get the exact cause of the interrupt and clear its source. When this bit is high, the interrupt signal from the MAC (sbd_intr_o) is high. **Value** — **Description** 0x0 — No Interrupt 0x1 — GMAC LPI Interrupt	RO	0x0
29	`tti`	This bit indicates an interrupt event in the Timestamp Generator block of EMAC. The software must read the corresponding registers in the EMAC to get the exact cause of interrupt and clear its source to reset this bit to 1'b0. When this bit is high, the interrupt signal from the EMAC subsystem (sbd_intr_o) is high. **Value** — **Description** 0x0 — No Interrupt 0x1 — Timestamp Trigger Interrupt	RO	0x0
27	`gmi`	This bit reflects an interrupt event in the MMC block of the EMAC. The software must read the corresponding registers in the EMAC to get the exact cause of interrupt and clear the source of interrupt to make this bit as 1'b0. The interrupt signal from the EMAC subsystem (sbd_intr_o) is high when this bit is high. **Value** — **Description** 0x0 — No Interrupt 0x1 — GMAC MMC Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
26	gli	This bit reflects an interrupt event in the PCS (link change and AN complete), SMII (link change), or RGMII (link change) interface block of the EMAC. The software must read the corresponding registers (Register 49 for PCS or Register 54 for SMII or RGMII) in the EMAC to get the exact cause of the interrupt and clear the source of interrupt to make this bit as 1'b0. The interrupt signal from the EMAC subsystem (sbd_intr_o) is high when this bit is high. **Value** — **Description** 0x0 — No Interrupt 0x1 — GMAC Line Interrupt	RO	0x0
25:23	eb	This field indicates the type of error that caused a Bus Error, for example, error response on the AHB or AXI interface. This field is valid only when Bit 13 (FBI) is set. This field does not generate an interrupt. * Bit 23 - 1'b1: Error during data transfer by the Tx DMA - 1'b0: Error during data transfer by the Rx DMA * Bit 24 - 1'b1: Error during read transfer - 1'b0: Error during write transfer * Bit 25 - 1'b1: Error during descriptor access - 1'b0: Error during data buffer access	RO	0x0
22:20	ts	This field indicates the Transmit DMA FSM state. This field does not generate an interrupt. **Value** — **Description** 0x0 — Stopped Reset or Stop Transmit Command 0x1 — Running: Fetching Tranmit Transfer Descriptor 0x2 — Running; Waiting for status 0x3 — Running; Reading Data host memory buffer and queuing it to transmit buffer (Tx FIFO) 0x4 — TIME_STAMP write state 0x5 — Reserved for future use 0x6 — Suspended; Transmit Descriptor Unavailable or Transmit Buffer Underflow 0x7 — Running; Closing Transmit Descriptor	RO	0x0

Bit	Name	Description	Access	Reset
19:17	`rs`	This field indicates the Receive DMA FSM state. This field does not generate an interrupt. **Value** **Description** 0x0 Stopped Reset or Stop Receive Command issued 0x1 Running: Fetching Receive Transfer Descriptor 0x2 Reserved for future use 0x3 Running: Waiting for receive packet 0x4 Suspended: Receive Descriptor Unavailable 0x5 Running: Closing Receive Descriptor 0x6 TIME_STAMP write state 0x7 Transferring rcv packet data from receive buffer to host memory	RO	0x0
16	`nis`	Normal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[0]: Transmit Interrupt * Register 5[2]: Transmit Buffer Unavailable * Register 5[6]: Receive Interrupt * Register 5[14]: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in Register 7) affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing 1 to this bit) each time a corresponding bit, which causes NIS to be set, is cleared.	RW	0x0
15	`ais`	Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[1]: Transmit Process Stopped * Register 5[3]: Transmit Jabber Timeout * Register 5[4]: Receive FIFO Overflow * Register 5[5]: Transmit Underflow * Register 5[7]: Receive Buffer Unavailable * Register 5[8]: Receive Process Stopped * Register 5[9]: Receive Watchdog Timeout * Register 5[10]: Early Transmit Interrupt * Register 5[13]: Fatal Bus Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit, which causes AIS to be set, is cleared.	RW	0x0

Bit	Name	Description	Access	Reset
14	eri	This bit indicates that the DMA had filled the first data buffer of the packet. Bit 6 (RI) of this register automatically clears this bit.	RW	0x0
13	fbi	This bit indicates that a bus error occurred, as described in Bits[25:23]. When this bit is set, the corresponding DMA engine disables all of its bus accesses.	RW	0x0
10	eti	This bit indicates that the frame to be transmitted is fully transferred to the MTL Transmit FIFO.	RW	0x0
9	rwt	This bit is asserted when a frame with length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).	RW	0x0
8	rps	This bit is asserted when the Receive Process enters the Stopped state.	RW	0x0
7	ru	This bit indicates that the host owns the Next Descriptor in the Receive List and the DMA cannot acquire it. The Receive Process is suspended. To resume processing Receive descriptors, the host should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, the Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor is owned by the DMA.	RW	0x0
6	ri	This bit indicates that the frame reception is complete. When reception is complete, the Bit 31 of RDES1 (Disable Interrupt on Completion) is reset in the last Descriptor, and the specific frame status information is updated in the descriptor. The reception remains in the Running state.	RW	0x0
5	unf	This bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.	RW	0x0
4	ovf	This bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11].	RW	0x0

Bit	Name	Description	Access	Reset
3	tjt	This bit indicates that the Transmit Jabber Timer expired, which happens when the frame size exceeds 2,048 (10,240 bytes when the Jumbo frame is enabled) . When the Jabber Timeout occurs, the transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.	RW	0x0
2	tu	This bit indicates that the host owns the Next Descriptor in the Transmit List and the DMA cannot acquire it. Transmission is suspended. Bits[22:20] explain the Transmit Process state transitions. To resume processing Transmit descriptors, the host should change the ownership of the descriptor by setting TDES0[31] and then issue a Transmit Poll Demand command.	RW	0x0
1	tps	This bit is set when the transmission is stopped.	RW	0x0
0	ti	This bit indicates that the frame transmission is complete. When transmission is complete, the Bit 31 (Interrupt on Completion) of TDES1 is reset in the first descriptor, and the specific frame status information is updated in the descriptor.	RW	0x0

Operation_Mode

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization.

Operation_Mode Fields

Bit	Name	Description	Access	Reset
26	dt	When this bit is set, the MAC does not drop the frames which only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors only in the encapsulated payload. When this bit is reset, all error frames are dropped if the FEF bit is reset. **Value** / **Description** 0x0 All Error Frames Dropped 0x1 MAC does not drop frame with errors	RW	0x0
25	rsf	When this bit is set, the MTL reads a frame from the Rx FIFO only after the complete frame has been written to it, ignoring the RTC bits. When this bit is reset, the Rx FIFO operates in the cut-through mode, subject to the threshold specified by the RTC bits. **Value** / **Description** 0x0 Rx Fifo cut-through mode 0x1 Read Rx FIFO only after complete frame	RW	0x0
24	dff	When this bit is set, the Rx DMA does not flush any frames because of the unavailability of receive descriptors or buffers as it does normally when this bit is reset. **Value** / **Description** 0x0 Rx DMA Flushed 0x1 Rx DMA not Flushed	RW	0x0
21	tsf	When this bit is set, transmission starts when a full frame resides in the MTL Transmit FIFO. When this bit is set, the TTC values specified in Bits[16:14] are ignored. This bit should be changed only when the transmission is stopped. **Value** / **Description** 0x0 Tx Does not Start with Full Frame 0x1 Tx Start with Full Frame	RW	0x0

Bit	Name	Description	Access	Reset
20	ftf	When this bit is set, the transmit FIFO controller logic is reset to its default values and thus all data in the Tx FIFO is lost or flushed. This bit is cleared internally when the flushing operation is completed. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation is complete only when the Tx FIFO is emptied of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. To complete this flush operation, the PHY transmit clock is required to be active. **Value** — **Description** 0x0 — Tx FIFO Data not Flushed 0x1 — TX FIFO Data Flushed	RW	0x0
16:14	ttc	These bits control the threshold level of the MTL Transmit FIFO. Transmission starts when the frame size within the MTL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when Bit 21 (TSF) is reset. **Value** — **Description** 0x0 — MTL Transmit FIFO Threshold 64 0x1 — MTL Transmit FIFO Threshold 128 0x2 — MTL Transmit FIFO Threshold 192 0x3 — MTL Transmit FIFO Threshold 256 0x4 — MTL Transmit FIFO Threshold 40 0x5 — MTL Transmit FIFO Threshold 32 0x6 — MTL Transmit FIFO Threshold 24 0x7 — MTL Transmit FIFO Threshold 16	RW	0x0

Bit	Name	Description	Access	Reset
13	st	When this bit is set, transmission is placed in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Register 4 (Transmit Descriptor List Address Register), or from the position retained when transmission was stopped previously. If the DMA does not own the current descriptor, transmission enters the Suspended state and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting Register 4 (Transmit Descriptor List Address Register), then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted. To change the list address, you need to program Register 4 (Transmit Descriptor List Address Register) with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state. **Value** — **Description** 0x0 — Transmission Stopped State 0x1 — Transmission in Run State	RW	0x0
12:11	rfd	These bits control the threshold (Fill-level of Rx FIFO) at which the flow control is de-asserted after activation. The de-assertion is effective only after flow control is asserted. **Value** — **Description** 0x0 — Full minus 1 KB 0x1 — Full minus 2 KB 0x2 — Full minus 3 KB 0x3 — Full minus 4 KB	RW	0x0

Bit	Name	Description	Access	Reset
10:9	`rfa`	These bits control the threshold (Fill level of Rx FIFO) at which the flow control is activated. These values only apply to the Rx FIFO when the EFC bit is set high. **Value** **Description** 0x0 Full minus 1 KB 0x1 Full minus 2 KB 0x2 Full minus 3 KB 0x3 Full minus 4 KB	`RW`	`0x0`
8	`efc`	When this bit is set, the flow control signal operation based on the fill-level of Rx FIFO is enabled. When reset, the flow control operation is disabled. **Value** **Description** 0x0 Rx FIFO Fill Level Disabled 0x1 Rx FIFO Fill Level Enabled Ctrl	`RW`	`0x0`
7	`fef`	When this bit is reset, the Rx FIFO drops frames with error status (CRC error, collision error, GMII_ER, giant frame, watchdog timeout, or overflow). However, if the start byte (write) pointer of a frame is already transferred to the read controller side (in Threshold mode), then the frame is not dropped. When the FEF bit is set, all frames except runt error frames are forwarded to the DMA. If the Bit 25 (RSF) is set and the Rx FIFO overflows when a partial frame is written, then the frame is dropped irrespective of the FEF bit setting. However, if the Bit 25 (RSF) is reset and the Rx FIFO overflows when a partial frame is written, then a partial frame may be forwarded to the DMA. **Value** **Description** 0x0 Drops Frames with error status 0x1 Forward all Frames(except runt)	`RW`	`0x0`

Bit	Name	Description	Access	Reset
6	fuf	When set, the Rx FIFO forwards Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC. When reset, the Rx FIFO drops all frames of less than 64 bytes, unless a frame is already transferred because of the lower value of Receive Threshold, for example, RTC = 01. **Value** **Description** 0x0 Drops Frames less than 64Bytes 0x1 Forward Frames with no errors	RW	0x0
4:3	rtc	These two bits control the threshold level of the MTL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MTL Receive FIFO is larger than the threshold. In addition, full frames with length less than the threshold are transferred automatically. These bits are valid only when the RSF bit is zero, and are ignored when the RSF bit is set to 1. **Value** **Description** 0x0 MTL Rcv Fifo threshold level 64 0x1 MTL Rcv Fifo threshold level 32 0x2 MTL Rcv Fifo threshold level 96 0x3 MTL Rcv Fifo threshold level 128	RW	0x0
2	osf	When this bit is set, it instructs the DMA to process the second frame of the Transmit data even before the status for the first frame is obtained. **Value** **Description** 0x0 DMA Does Not Process second frame 0x1 DMA Processes second frame	RW	0x0

Bit	Name	Description	Access	Reset
1	sr	When this bit is set, the Receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes the incoming frames. The descriptor acquisition is attempted from the current position in the list, which is the address set by Register 3 (Receive Descriptor List Address Register) or the position retained when the Receive process was previously stopped. If the DMA does not own the descriptor, reception is suspended and Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set. The Start Receive command is effective only when the reception has stopped. If the command is issued before setting Register 3 (Receive Descriptor List Address Register), the DMA behavior is unpredictable. When this bit is cleared, the Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state. **Value** — **Description** 0x0 — Rx DMA operation is stopped 0x1 — Rx DMA operation is started	RW	0x0

Interrupt_Enable

The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Bit	Name	Description	Access	Reset
6	rie	When this bit is set with Normal Interrupt Summary Enable (Bit 16), the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled. **Value** **Description** 0x0 Receive Interrupt Disabled 0x1 Receive Interrupt Enabled	RW	0x0
5	une	When this bit is set with Abnormal Interrupt Summary Enable (Bit 15), the Transmit Underflow Interrupt is enabled. When this bit is reset, the Underflow Interrupt is disabled. **Value** **Description** 0x0 Underflow Interrupt Disabled 0x1 Underflow Interrupt Enabled	RW	0x0
4	ove	When this bit is set with Abnormal Interrupt Summary Enable (Bit 15), the Receive Overflow Interrupt is enabled. When this bit is reset, the Overflow Interrupt is disabled. **Value** **Description** 0x0 Transmit Overflow Interrupt Disabled 0x1 Transmit Overflow Interrupt Enabled	RW	0x0
3	tje	When this bit is set with Abnormal Interrupt Summary Enable (Bit 15), the Transmit Jabber Timeout Interrupt is enabled. When this bit is reset, the Transmit Jabber Timeout Interrupt is disabled. **Value** **Description** 0x0 Transmit Jabber Timeout Interrupt Disabled 0x1 Transmit Jabber Timeout Interrupt Enabled	RW	0x0

Bit	Name	Description	Access	Reset
2	tue	When this bit is set with Normal Interrupt Summary Enable (Bit 16), the Transmit Buffer Unavailable Interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable Interrupt is disabled. **Value** **Description** 0x0 Transmit Buffer Unavailable Interrupt Disabled 0x1 Transmit Buffer Unavailable Interrupt Enabled	RW	0x0
1	tse	When this bit is set with Abnormal Interrupt Summary Enable (Bit 15), the Transmission Stopped Interrupt is enabled. When this bit is reset, the Transmission Stopped Interrupt is disabled. **Value** **Description** 0x0 Transmit Stopped Interrupt Disabled 0x1 Transmit Stopped Interrupt Enabled	RW	0x0
0	tie	When this bit is set with Normal Interrupt Summary Enable (Bit 16), the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled. **Value** **Description** 0x0 Transmit Interrupt Disabled 0x1 Transmit Interrupt Enabled	RW	0x0

Missed_Frame_And_Buffer_Overflow_Counter

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF701020
emac1	0xFF702000	0xFF703020

Offset: 0x1020

Access: RO

Bit Fields

misfrmcnt RO 0x0															

Missed_Frame_And_Buffer_Overflow_Counter Fields

Bit	Name	Description	Access	Reset
28	ovfcntovf	Overflow bit for FIFO Overflow Counter	RO	0x0
27:17	ovffrmcnt	This field indicates the number of frames missed by the application. This counter is incremented each time the MTL asserts the sideband signal mtl_rxoverflow_o. The counter is cleared when this register is read with mci_be_i[2] at 1'b1.	RO	0x0
16	miscntovf	Overflow bit for Missed Frame Counter	RO	0x0
15:0	misfrmcnt	This field indicates the number of frames missed by the controller because of the Host Receive Buffer being unavailable. This counter is incremented each time the DMA discards an incoming frame. The counter is cleared when this register is read with mci_be_i[0] at 1'b1.	RO	0x0

Receive_Interrupt_Watchdog_Timer

This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of Register 5 (Status Register)

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF701024
emac1	0xFF702000	0xFF703024

Offset: 0x1024

Access: RW

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								riwt RW 0x0							

Receive_Interrupt_Watchdog_Timer Fields

Bit	Name	Description	Access	Reset
7:0	riwt	This bit indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per RDES1[31] of any received frame.	RW	0x0

AXI_Bus_Mode

The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF701028
emac1	0xFF702000	0xFF703028

AXI_Bus_Mode Fields

Bit	Name	Description	Access	Reset
31	en_lpi	When set to 1, this bit enables the LPI mode supported by the AXI master and accepts the LPI request from the AXI System Clock controller. When set to 0, this bit disables the LPI mode and always denies the LPI request from the AXI System Clock controller. **Value** **Description** 0x0 Disable LPI Mode 0x1 Enable LPI Mode	RW	0x0
30	lpi_xit_frm	When set to 1, this bit enables the GMAC-AXI to come out of the LPI mode only when the Magic Packet or Remote Wake Up Packet is received. When set to 0, this bit enables the GMAC-AXI to come out of LPI mode when any frame is received. **Value** **Description** 0x0 Do Not exit LPI Mode with Magic Packet 0x1 Exit LPI Mode with Magic Packet	RW	0x0
23:20	wr_osr_lmt	AXI Maximum Write OutStanding Request Limit	RW	0x1
19:16	rd_osr_lmt	This value limits the maximum outstanding request on the AXI read interface. Maximum outstanding requests = RD_OSR_LMT+1	RW	0x1
13	onekbbe	1 KB Boundary Crossing Enable for the GMAC-AXI Master When set, the GMAC-AXI Master performs burst transfers that do not cross 1 KB boundary. When reset, the GMAC-AXI Master performs burst transfers that do not cross 4 KB boundary. **Value** **Description** 0x0 4K boundary 0x1 1K boundary	RW	0x0

Bit	Name	Description	Access	Reset
12	`axi_aal`	This bit is read-only bit and reflects the Bit 25 (AAL) of Register 0 (Bus Mode Register). When this bit is set to 1, the GMAC-AXI performs address-aligned burst transfers on both read and write channels. **Value** — **Description** 0x0 — No Address-Alignment Bursts 0x1 — Address-Alignmnet Bursts	RO	0x0
3	`blen16`	When this bit is set to 1 or UNDEFINED is set to 1, the GMAC-AXI is allowed to select a burst length of 16 on the AXI Master interface. **Value** — **Description** 0x0 — AXI No Fixed Busrts 0x1 — AXI Fixed Burst BLEN = 16	RW	0x0
2	`blen8`	When this bit is set to 1, the GMAC-AXI is allowed to select a burst length of 8 on the AXI Master interface. Setting this bit has no effect when UNDEFINED is set to 1. **Value** — **Description** 0x0 — AXI No Fixed Busrts 0x1 — AXI Fixed Burst BLEN = 8	RW	0x0
1	`blen4`	When this bit is set to 1, the GMAC-AXI is allowed to select a burst length of 4 on the AXI Master interface. Setting this bit has no effect when UNDEFINED is set to 1. **Value** — **Description** 0x0 — AXI No Fixed Busrts 0x1 — AXI Fixed Burst BLEN = 4	RW	0x0

Bit	Name	Description	Access	Reset
0	`undefined`	This bit is read-only bit and indicates the complement (invert) value of Bit 16 (FB) in Register 0 (Bus Mode Register[16]). * When this bit is set to 1, the GMAC-AXI is allowed to perform any burst length equal to or below the maximum allowed burst length programmed in Bits[7:1]. * When this bit is set to 0, the GMAC-AXI is allowed to perform only fixed burst lengths as indicated by BLEN16, BLEN8, or BLEN4, or a burst length of 1. **Value** / **Description** 0x0 Fixed Burst Lengths 4 to 32 0x1 Any Burst Length up to max	RO	0x1

AHB_or_AXI_Status

This register provides the active status of the AXI interface's read and write channels. This register is useful for debugging purposes. In addition, this register is valid only in the Channel 0 DMA when multiple channels are present in the AV mode.

Module Instance	Base Address	Register Address

Document Revision History

Table 17-21: Document Revision History

Date	Version	Changes
June 2014	2014.06.30	Updated EMAC to RGMII Interface table with EMAC Port names Updated EMAC to FPGA PHY Interface table with Signal names Updated EMAC to FPGA IEEE1588 Timestamp Interface with Signal names Added Address Map and Register Descriptions
February 2014	2014.02.28	ECC updates.
December 2013	1.4	Maintenance release.
November 2012	1.3	• Expanded shared memory block table. • Added CSEL tables. • Additional minor updates.
June 2012	1.2	Updated the HPS boot and FPGA configuration sections.

USB 2.0 OTG Controller 18

2014.07.31

cv_54018 Subscribe Send Feedback

The hard processor system (HPS) provides two instances of a USB On-The-Go (OTG) controller that supports both device and host functions. The controller supports all high-speed, full-speed, and low-speed transfers in both device and host modes. The controller is fully compliant with the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The controller can be programmed for both device and host functions to support data movement over the USB protocol.

The controllers are operationally independent of each other. Each USB OTG controller supports a single USB port connected through a USB 2.0 Transceiver Macrocell Interface Plus (UTMI+) Low Pin Interface (ULPI) compliant PHY. The USB OTG controllers are instances of the Synopsys® [†]DesignWare® Cores USB 2.0 Hi-Speed On-The-Go (DWC_otg) controller.

The USB OTG controller is optimized for the following applications and systems: †

- Portable electronic devices †
- Point-to-point applications (no hub, direct connection to HS, FS, or LS device) †
- Multi-point applications (as an embedded USB host) to devices (hub and split support) †

Each of the two USB OTG ports supports both host and device modes, as described in the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The USB OTG ports support connections for all types of USB peripherals, including the following peripherals:

- Mouse
- Keyboard
- Digital cameras
- Network adapters
- Hard drives
- Generic hubs

Additional information is available in the On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification, which you can download from the USB Implementers Forum website

Features of the USB OTG Controller

The USB OTG controller has the following USB-specific features:

- Complies with both Revision 1.3 and Revision 2.0 of the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*
- Supports software-configurable modes of operation between OTG 1.3 and OTG 2.0
- Supports all USB 2.0 speeds:
  - High speed (HS, 480-Mbps)
  - Full speed (FS, 12-Mbps)
  - Low speed (LS, 1.5-Mbps)

  Note: In host mode, all speeds are supported. However, in device mode, only high speed and full speed are supported.
- Supports all USB transaction types:
  - Control transfers
  - Bulk transfers
  - Isochronous transfers
  - Interrupts
- Supports automatic ping capability
- Supports Session Request Protocol (SRP) and Host Negotiation Protocol (HNP)
- Supports suspend, resume, and remote wake
- Supports up to 16 host channels

  Note: In host mode, when the number of device endpoints is greater than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.
- Supports up to 16 bidirectional endpoints, including control endpoint 0

  Note: Only seven periodic device IN endpoints are supported.
- Supports a generic root hub
- Performs transaction scheduling in hardware

On the USB PHY layer, the USB OTG controller supports the following features:

- A single USB port connected to each OTG instance
- A ULPI connection to an off-chip USB transceiver
- Software-controlled access, supporting vendor-specific or optional PHY registers access to ease debug
- The OTG 2.0 support for Attach Detection Protocol (ADP) only through an external (off-chip) ADP controller

On the integration side, the USB OTG controller supports the following features:

- Different clocks for system and PHY interfaces
- Dedicated TX FIFO buffer for each device IN endpoint in direct memory access (DMA) mode
- Packet-based, dynamic FIFO memory allocation for endpoints for small FIFO buffers and flexible, efficient use of RAM that can be dynamically sized by software
- Ability to change an endpoint's FIFO memory size during transfers
- Clock gating support during USB suspend and session-off modes
    - PHY clock gating support
    - System clock gating support
- Data FIFO RAM clock gating support
- Local buffering with error correction code (ECC) support

Note: The USB OTG controller does not support the following protocols:

- Enhanced Host Controller Interface (EHCI)
- Open Host Controller Interface (OHCI)
- Universal Host Controller Interface (UHCI)

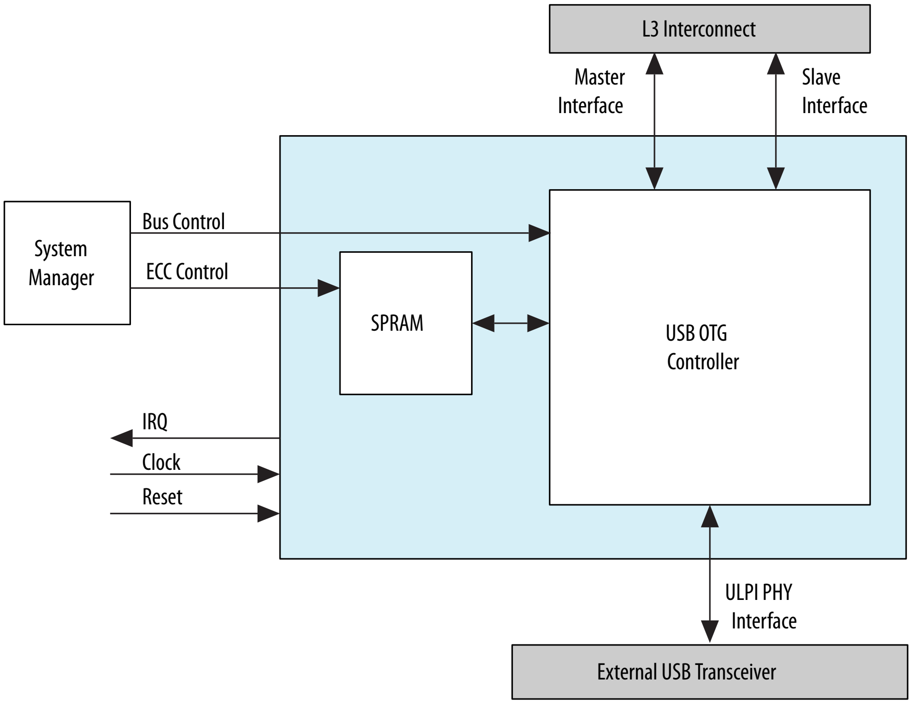
Supported PHYS

The USB OTG controller supports USB 2.0 ULPI PHYs. Only the single data rate (SDR) mode is supported. Refer to the *Cyclone V Device Datasheet* for timing characteristics on the USB PHY interface. The Altera *Cyclone V* SoC Development Board currently uses a SMSC USB3300 PHY.

USB OTG Controller Block Diagram and System Integration

Figure 18-1: USB OTG Controller System Integration

Two subsystems are included in the HPS.



The USB OTG controller connects to the level 3 (L3) interconnect through a slave interface, allowing other masters to access the control and status registers (CSRs) in the controller. The controller also connects to the L3 interconnect through a master interface, allowing the DMA engine in the controller to move data between external memory and the controller.

A single-port RAM (SPRAM) connected to the USB OTG controller is used to store USB data packets for both host and device modes. It is configured as FIFO buffers for receive and transmit data packets on the USB link.

Through the system manager, the USB OTG controller has control to use and test error correction codes (ECCs) in the SPRAM. Through the system manager, the USB OTG controller can also control the behavior of the master interface to the L3 interconnect.

The USB OTG controller connects to the external USB transceiver through a ULPI PHY interface. This interface also connects through pin multiplexers within the HPS. The pin multiplexers are controlled by the system manager.

Additional connections on the USB OTG controller include:

- Clock input from the clock manager to the USB OTG controller
- Reset input from the reset manager to the USB OTG controller
- Interrupt line from the USB OTG controller to the microprocessor unit (MPU) global interrupt controller (GIC).

System Manager

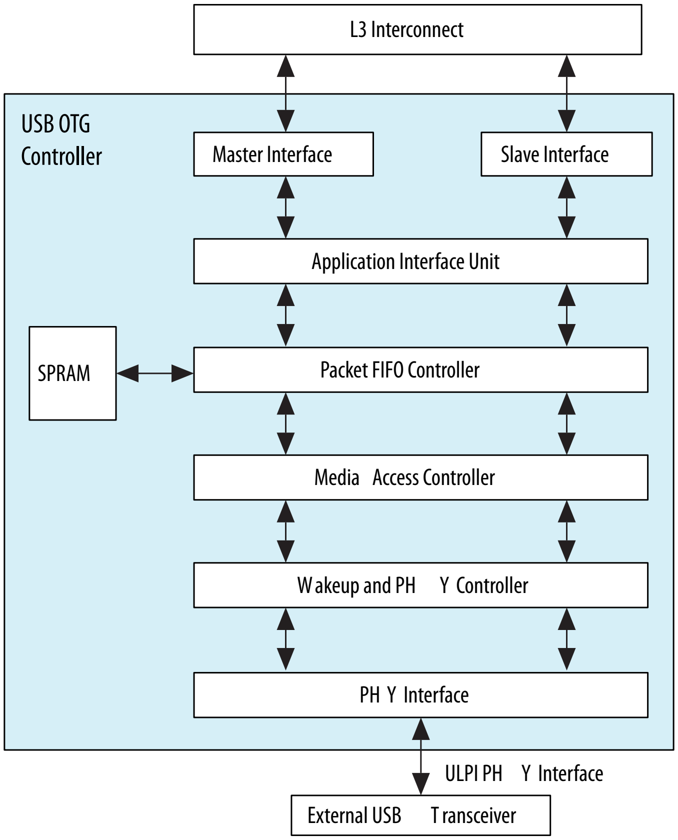
Details available in the System Manager chapter.

Functional Description of the USB OTG Controller

USB OTG Controller Block Description

Figure 18-2: USB OTG Controller Block Description

Details about each of the units that comprise the USB OTG controller are shown below.



Master Interface

The master interface includes a built-in DMA controller. The DMA controller moves data between external memory and the media access controller (MAC).

Properties of the master interface are controlled through the USB L3 Master HPROT Register (`l3master`) in the system manager. These bits provide access information to the L3 interconnect, including whether or not transactions are cacheable, bufferable, or privileged.

Note: Bits in the `l3master` register can be updated only when the master interface is guaranteed to be in an inactive state.

Slave Interface

The slave interface allows other masters in the system to access the USB OTG controller's CSRs. For testing purposes, other masters can also access the SPRAM.

Slave Interface CSR Unit

The slave interface can read from and write to all the CSRs in the USB OTG controllers. All register accesses are 32 bits.

The CSR is divided into the following groups of registers:

- Global
- Host
- Device
- Power and clock gating

Some registers are shared between host and device modes, because the controller can only be in one mode at a time. The controller generates a mode mismatch interrupt if a master attempts to access device registers when the controller is in host mode, or attempts to access host registers when the controller is in device mode. Writing to unimplemented registers is ignored. Reading from unimplemented registers returns indeterminate values.

Application Interface Unit

The application interface unit (AIU) generates DMA requests based on programmable FIFO buffer thresholds. The AIU generates interrupts to the GIC for both host and device modes. A DMA scheduler is included in the AIU to arbitrate and control the data transfer between packets in system memory and their respective USB endpoints.

Packet FIFO Controller

The Packet FIFO Controller (PFC) connects the AIU with the MAC through data FIFO buffers located in the SPRAM. In device mode, one FIFO buffer is implemented for each IN endpoint. In host mode, a single FIFO buffer stores data for all periodic (isochronous and interrupt) OUT endpoints, and a single FIFO buffer is used for nonperiodic (control and bulk) OUT endpoints. Host and device mode share a single receive data FIFO buffer.

SPRAM

An SPRAM implements the data FIFO buffers for host and device modes. The size of the FIFO buffers can be programmed dynamically.

The SPRAM supports ECCs. ECCs can be enabled through the system manager, by setting the RAM ECC Enable (`en`) bit in the USB0 or USB1 RAM ECC Enable Register (`usb0` or `usb1`), in the ECC Management Register Group (`eccgrp`). Single-bit and double-bit errors in each USB instance can be injected using this register.

The SPRAM provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected), and when double-bit (uncorrectable) errors are detected. The system manager generates an interrupt to the GIC when an ECC error is detected.

MAC

The MAC module implements the following functionality:

- USB transaction support
- Host protocol support
- Device protocol support
- OTG protocol support
- Link power management (LPM) functions

USB Transactions

In device mode, the MAC decodes and checks the integrity of all token packets. For valid OUT or SETUP tokens, the following DATA packet is also checked. If the data packet is valid, the MAC performs the following steps:

1. Writes the data to the receive FIFO buffer
2. Sends the appropriate handshake when required to the USB host

If a receive FIFO buffer is not available, the MAC sends a NAK response to the host. The MAC also supports ping protocol.

For IN tokens, if data is available in the transmit FIFO buffer, the MAC performs the following steps:

1. Reads the data from the FIFO buffer
2. Forms the data packet
3. Transmits the packet to the host
4. Receives the response from the host
5. Sends the updated status to the PFC

In host mode, the MAC receives a token request from the AIU. The MAC performs the following steps:

1. Builds the token packet
2. Sends the packet to the device

For OUT or SETUP transactions, the MAC also performs the following steps:

1. Reads the data from the transmit FIFO buffer
2. Assembles the data packet
3. Sends the packet to the device
4. Waits for a response

The response from the device causes the MAC to send a status update to the AIU.

For IN or PING transactions, the MAC waits for the data or handshake response from the device. For data responses, the MAC performs the following steps:

1. Validates the data
2. Writes the data to the receive FIFO buffer
3. Sends a status update to the AIU
4. Sends a handshake to the device, if appropriate

Host Protocol

In host mode, the MAC performs the following functions:

- Detects connect, disconnect, and remote wakeup events on the USB link
- Initiates reset
- Initiates speed enumeration processes
- Generates Start of Frame (SOF) packets.

Device Protocol

In device mode, the MAC performs the following functions:

- Handles USB reset sequence
- Handles speed enumeration
- Detects USB suspend and resume activity on the USB link
- Initiates remote wakeup
- Decodes SOF packets

OTG Protocol

The MAC handles HNP and SRP for OTG operation. HNP provides a mechanism for swapping host and device roles. SRP provides mechanisms for the host to turn off V_{BUS} to save power, and for a device to request a new USB session.

LPM Functions

The USB OTG controller supports LPM in both host and device modes. With this feature, the USB OTG controller can enter a sleep state when a successful LPM transaction occurs on the USB link.

Wakeup and Power Control

To reduce power, the USB OTG controller supports a power-down mode. In power-down mode, the controller and the PHY can shut down their clocks. The controller supports wakeup on the detection of the following events:

- Resume
- Remote wakeup
- Session request protocol
- New session start

PHY Interface Unit

The USB OTG controller supports synchronous SDR data transmission to a ULPI PHY. The SDR mode implements an eight-bit data bus.

ULPI PHY Interface

Table 18-1: ULPI PHY Interfaces

The ULPI PHY interface is synchronous to the `ulpi_clk` signal coming from the PHY.

Port Name	Bit Width	Direction	Description
`ulpi_clk`	1	Input	ULPI Clock Receives the 60-MHz clock supplied by the high-speed ULPI PHY. All signals are synchronous to the positive edge of the clock.
`ulpi_dir`	1	Input	ULPI Data Bus Control 1—The PHY has data to transfer to the USB OTG controller. 0—The PHY does not have data to transfer.
`ulpi_nxt`	1	Input	ULPI Next Data Control Indicates that the PHY has accepted the current byte from the USB OTG controller. When the PHY is transmitting, this signal indicates that a new byte is available for the controller.
`ulpi_stp`	1	Output	ULPI Stop Data Control The controller drives this signal high to indicate the end of its data stream. The controller can also drive this signal high to request data from the PHY.
`ulpi_data[7:0]`	8	Bidirectional	Bidirectional data bus. Driven low by the controller during idle.

Clocks

Table 18-2: USB OTG Controller Clock Inputs

All clocks must be operational when reset is released. No special handling is required on the clocks.

Clock Signal	Frequency	Functional Usage
`usb_mp_clk`	60 – 200 MHz	Drives the master and slave interfaces, DMA controller, and internal FIFO buffers
`usb0_ulpi_clk`	60 MHz	ULPI reference clock for usb0 from external ULPI PHY I/O pin
`usb1_ulpi_clk`	60 MHz	ULPI reference clock for usb1 from external ULPI PHY I/O pin

Resets

The USB OTG controller can be reset either through the hardware reset input or through software.

Reset Requirements

There must be a minimum of 12 cycles on the `ulpi_clk` clock before the controller is taken out of reset. During reset, the USB OTG controller asserts the `ulpi_stp` signal. The PHY outputs a clock when it sees the `ulpi_stp` signal asserted. However, if the pin multiplexers are not programmed, the PHY does not see the `ulpi_stp` signal. As a result, the `ulpi_clk` clock signal does not arrive at the USB OTG controller.

Software must ensure that the reset is active for a minimum of two `usb_mp_c lk` cycles. There is no maximum assertion time.

Hardware Reset

Each of the USB OTG controllers has one reset input from the reset manager. The reset signal is asserted during a cold or warm reset event. The reset manager holds the controllers in reset until software releases the resets. Software releases resets by clearing the appropriate USB bits in the Peripheral Module Reset Register (`permodrst`) in the HPS reset manager.

The reset input resets the following blocks:

- The master and slave interface logic
- The integrated DMA controller
- The internal FIFO buffers
- The CSR

The reset input is synchronized to the `usb_mp_clk` domain. The reset input is also synchronized to the ULPI clock within the USB OTG controller and is used to reset the ULPI PHY domain logic.

Software Reset

Software can reset the controller by setting the Core Soft Reset (`csftrst`) bit in the Reset Register (`grstctl`) in the Global Registers (`globgrp`) group of the USB OTG controller.

Software resets are useful in the following situations:

- A PHY selection bit is changed by software. Resetting the USB OTG controller is part of clean-up to ensure that the PHY can operate with the new configuration or clock.
- During software development and debugging.

Interrupts

Table 18-3: USB OTG Interrupt Conditions

Each USB OTG controller has a single interrupt output. Interrupts are asserted on the conditions shown in the following table.

Condition	Mode
Device-initiated remote wakeup is detected.	Host mode
Session request is detected from the device.	Host mode

Condition	Mode
Device disconnect is detected.	Host mode
Host LPM entry retry has expired or LPM transaction(s) are complete.	Host mode
Host periodic TX FIFO buffer is empty (can be further programmed to indicate half-empty).	Host mode
Host channels interrupt received.	Host mode
Incomplete periodic transfer is pending at the end of the microframe.	Host mode
Host port status interrupt received.	Host mode
External host initiated resume is detected.	Device mode
LPM handshake is sent.	Device mode
Reset is detected when in suspend or normal mode.	Device mode
USB suspend mode is detected.	Device mode
Data fetch is suspended due to TX FIFO buffer full or request queue full.	Device mode
At least one isochronous OUT endpoint is pending at the end of the microframe.	Device mode
At least one isochronous IN endpoint is pending at the end of the microframe.	Device mode
At least one IN or OUT endpoint interrupt is pending at the end of the microframe.	Device mode
The end of the periodic frame is reached.	Device mode
Failure to write an isochronous OUT packet to the RX FIFO buffer. The RX FIFO buffer does not have enough space to accommodate the maximum packet size for the isochronous OUT endpoint.	Device mode
Enumeration has completed.	Device mode
Connector ID change.	Common modes
Mode mismatch. Software accesses registers belonging to an incorrect mode.	Common modes
Nonperiodic TX FIFO buffer is empty.	Common modes

Condition	Mode
RX FIFO buffer is not empty.	Common modes
Start of microframe.	Common modes
Device connection debounce is complete in host mode.	OTG interrupts
A-Device timeout while waiting for B-Device connection.	OTG interrupts
Host negotiation is complete.	OTG interrupts
Session request is complete.	OTG interrupts
Session end is detected in device mode.	OTG interrupts

USB OTG Controller Programming Model

For detailed information about using the USB OTG controller, consult your operating system (OS) driver documentation. The OS vendor provides application programming interfaces (APIs) to control USB host, device and OTG operation. This section provides a brief overview of the following software operations:

- Enabling SPRAM ECCs
- Host operation
- Device operation

Enabling SPRAM ECCs

To avoid false ECC errors, you must initialize the ECC bits in the SPRAM before using ECCs. To initialize the ECC bits, software writes data to all locations in the SPRAM.

The L3 interconnect has access to the SPRAM and is accessible through the USB OTG L3 slave interface. Software accesses the SPRAM through the `directfifo` memory space, in the USB OTG controller address space.

The SPRAM contains 8192 (32 KB) locations. The L3 slave provides 32-bit access to the SPRAM. Physically, the SPRAM is implemented as a 35-bit memory, with the highest three bits reserved for the USB OTG controller's internal use. When a write is performed to the SPRAM through the L3 slave interface, bits 32 through 34 of the internal data bus are tied to 1, to enable the ECC bits to be initialized.

Note: Software cannot access the SPRAM beyond the 32-KB range. Out-of-range read transactions return indeterminate data. Out-of-range write transactions are ignored.

Related Information

USB OTG Controller Address Map and Register Definitions on page 18-15
The directfifo memory space is described in the controller address map.

Host Operation

Host Initialization

After power up, the USB port is in its default mode. No VBUS is applied to the USB cable. The following process sets up the USB OTG controller as a USB host.

1. To enable power to the USB port, the software driver sets the Port Power (`prtpwr`) bit to 1 in the Host Port Control and Status Register (`hprt`) of the Host Mode Registers (`hostgrp`) group. This action drives the V_{BUS} signal on the USB link.

   The controller waits for a connection to be detected on the USB link.
2. When a USB device connects, an interrupt is generated. The Port Connect Detected (`PrtConnDe t`) bit in `hprt` is set to 1.
3. Upon detecting a port connection, the software driver initiates a port reset by setting the Port Reset (`prtrst`) bit to 1 in `hprt`.
4. The software driver must wait a minimum of 10 ms so that speed enumeration can complete on the USB link.
5. After the 10 ms, the software driver sets `prtrst` back to 0 to release the port reset.
6. The USB OTG controller generates an interrupt. The Port Enable Disable Change (`prtenchng`) and Port Speed (`prtspd`) bits, in `hprt`, are set to reflect the enumerated speed of the device that attached.

   At this point the port is enabled for communication. Keep alive or SOF packets are sent on the port. If a USB 2.0-capable device fails to initialize correctly, it is reported as a USB 1.1 device.

   The Host Frame Interval Register (`hfir`) is updated with the corresponding PHY clock settings. The `hfir`, used for sending SOF packets, is in the Host Mode Registers (`host grp`) group.
7. The software driver must program the following registers in the Global Registers (`globgrp`) group, in the order listed:

   a. Receive FIFO Size Register (`grxfsiz`)—selects the size of the receive FIFO buffer
   b. Non-periodic Transmit FIFO Size Register (`gnptxfsiz`)—selects the size and the start address of the non-periodic transmit FIFO buffer for nonperiodic transactions
   c. Host Periodic Transmit FIFO Size Register (`hptxfsiz`)—selects the size and start address of the periodic transmit FIFO buffer for periodic transactions
8. System software initializes and enables at least one channel to communicate with the USB device.

Host Transaction

When configured as a host, the USB OTG controller pipes the USB transactions through one of two request queues (one for periodic transactions and one for nonperiodic transactions). Each entry in the request queue holds the SETUP, IN, or OUT channel number along with other information required to perform a transaction on the USB link. The sequence in which the requests are written to the queue determines the sequence of transactions on the USB link.

The host processes the requests in the following order at the beginning of each frame or microframe:

1. Periodic request queue, including isochronous and interrupt transactions
2. Nonperiodic request queue (bulk or control transfers)

The host schedules transactions for each enabled channel in round-robin fashion. When the host controller completes the transfer for a channel, the controller updates the DMA descriptor status in the system memory.

For OUT transactions, the host controller uses two transmit FIFO buffers to hold the packet payload to be transmitted. One transmit FIFO buffer is used for all nonperiodic OUT transactions and the other is used for all periodic OUT transactions.

For IN transactions, the USB host controller uses one receive FIFO buffer for all periodic and nonperiodic transactions. The controller holds the packet payload from the USB device in the receive FIFO buffer until the packet is transferred to the system memory. The receive FIFO buffer also holds the status of each packet received. The status entry holds the IN channel number along with other information, including received byte count and validity status.

For generic hub operations, the USB OTG controller uses SPLIT transfers to communicate with slower-speed devices downstream of the hub. For these transfers, the transaction accumulation or buffering is performed in the generic hub, and is scheduled accordingly. The USB OTG controller ensures that enough transmit and receive buffers are allocated when the downstream transactions are completed or when accumulated data is ready to be sent upstream.

Device Operation

Device Initialization

The following process sets up the USB OTG controller as a USB device:

1. After power up, the USB OTG controller must be set to the desired device speed by writing to the Device Speed (`devspd`) bits in the Device Configuration Register (`dcfg`) in the Device Mode Registers (`devgrp`) group. After the device speed is set, the controller waits for a USB host to detect the USB port as a device port.
2. When an external host detects the USB port, the host performs a port reset, which generates an interrupt to the USB device software. The USB Reset (`usbrst`) bit in the Interrupt (`port reset`) register in the Global Registers (`globgrp`) group is set. The device software then sets up the data FIFO buffer to receive a SETUP packet from the external host. Endpoint 0 is not enabled yet.
3. After completion of the port reset, the operation speed required by the external host is known. Software reads the device speed status and sets up all the remaining required transaction fields to enable control endpoint 0.

After completion of this process, the device is receiving SOF packets, and is ready for the USB host to set up the device’s control endpoint.

Device Transaction

When configured as a device, the USB OTG controller uses a single FIFO buffer to receive the data for all the OUT endpoints. The receive FIFO buffer holds the status of the received data packet, including the byte count, the data packet ID (PID), and the validity of the received data. The DMA controller reads the data out of the FIFO buffer as the data are received. If a FIFO buffer overflow condition occurs, the controller responds to the OUT packet with a NAK, and internally rewinds the pointers.

For IN endpoints, the controller uses dedicated transmit buffers for each endpoint. The application does not need to predict the order in which the USB host will access the nonperiodic endpoints. If a FIFO buffer underrun condition occurs during transmit, the controller inverts the cyclic redundancy code (CRC) to mark the packet as corrupt on the USB link.

The application handles one data packet at a time per endpoint in transaction-level operations. The software receives an interrupt on completion of every packet. Based on the handshake response received on the USB link, the application determines whether to retry the transaction or proceed with the next transaction, until all packets in the transfer are completed.

IN Transactions

For an IN transaction, the application performs the following steps:

1. Enables the endpoint
2. Triggers the DMA engine to write the associated data packet to the corresponding transmit FIFO buffer
3. Waits for the packet completion interrupt from the controller

When an IN token is received on an endpoint when the associated transmit FIFO buffer does not contain sufficient data, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to the USB host

If sufficient data is available, the controller transmits the data to the USB host.

OUT Transactions

For an OUT transaction, the application performs the following steps:

1. Enables the endpoint
2. Waits for the packet received interrupt from the USB OTG controller
3. Retrieves the packet from the receive FIFO buffer

When an OUT token or PING token is received on an endpoint where the receive FIFO buffer does not have sufficient space, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to USB host

If sufficient space is available, the controller stores the data in the receive FIFO buffer and returns an ACK handshake to the USB link.

Control Transfers

For control transfers, the application performs the following steps:

1. Waits for the packet received interrupt from the controller
2. Retrieves the packet from the receive buffer

Because the control transfer is governed by USB protocol, the controller always responds with an ACK handshake.

USB OTG Controller Address Map and Register Definitions

The address map and register definitions for the USB OTG Controller consist of the following regions:

- USB OTG Controller Module 0 Registers
- USB OTG Controller Module 1 Registers

USB OTG Controller Module Registers Address Map on page 18-16
Registers in the USB OTG Controller Module. Only the Core Global, Power and Clock Gating, Data FIFO Access, and Host Port registers can be accessedin both Host and Device modes. When the USB OTG Controller is operating in one mode, either Device or Host, the application must not access registers from the other mode. If an illegal access occurs, a Mode Mismatch interrupt is generated and reflected in the Core Interrupt register (GINTSTS.ModeMis). When the core switches from one mode to another, the registers in the new mode must be reprogrammed as they would be after a power-on reset. The register address map is fixed and does not depend on the module configuration (for example, how many endpoints are implemented). Host and Device mode registers occupy different addresses.

EP15/HC15 FIFO	This address space is allocated for Endpoint 15/Host Channel 15 push/pop FIFO access.	0x10000	0x10FFF

USB Direct Access FIFO RAM Address Map

Name	Description	Start Address Offset	End Address Offset
`Direct_FIFO`	This address space is allocated for directly accessing the data FIFO for debugging purposes.	`0x20000`	`0x3FFFF`

Global Registers Register Descriptions

These registers are available in both Host and Device modes, and do not need to be reprogrammed when switching between these modes.

Offset: `0x0`

gotgctl on page 18-39
The OTG Control and Status register controls the behavior and reflects the status of the OTG function.

gotgint on page 18-45
The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

gahbcfg on page 18-47
This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

gusbcfg on page 18-51
This register can be used to configure the core after power-on or a changing to Host mode or Device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

grstctl on page 18-56
The application uses this register to reset various hardware features inside the core

gintsts on page 18-60
This register interrupts the application for system-level events in the current mode (Device mode or Host mode). Some of the bits in this register are valid only in Host mode, while others are valid in Device mode only. This register also indicates the current mode. To clear the interrupt status bits of type R_SS_WC, the application must write 1 into the bit. The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically. The application must clear the GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

gintmsk on page 18-69
This register works with the Interrupt Register (GINTSTS) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the GINTSTS register bit corresponding to that interrupt is still set.

grxstsr on page 18-74
A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the RxFIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.

grxstsp on page 18-75
A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the RxFIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register'ss reset value before configuring the core because the read value is "X" in the simulation.

grxfsiz on page 18-77
The application can program the RAM size that must be allocated to the RxFIFO.

gnptxfsiz on page 18-78
The application can program the RAM size and the memory start address for the Non-periodic TxFIFO. The fields of this register change, depending on host or device mode.

gnptxsts on page 18-78
In Device mode, this register is valid only in Shared FIFO operation. It contains the free space information for the Non-periodic TxFIFO and the Nonperiodic Transmit RequestQueue

gpvndctl on page 18-80
The application can use this register to access PHY registers. for a ULPI PHY, the core uses the ULPI interface for PHY register access. The application sets Vendor Control register for PHY register access and times the PHY register access. The application polls the VStatus Done bit in this register for the completion of the PHY register access

ggpio on page 18-81
The application can use this register for general purpose input/output ports or for debugging.

guid on page 18-82
This is a read/write register containing the User ID. This register can be used in the following ways: -To store the version or revision of your system -To store hardware configurations that are outside the otg core As a scratch register

gsnpsid on page 18-83
This read-only register contains the release number of the core being used.

ghwcfg1 on page 18-83
This register contains the logical endpoint direction(s).

ghwcfg2 on page 18-84
This register contains configuration options.

ghwcfg3 on page 18-88
This register contains the configuration options.

ghwcfg4 on page 18-90
This register contains the configuration options.

gdfifocfg on page 18-95
Specifies whether Dedicated Transmit FIFOs should be enabled in device mode.

hptxfsiz on page 18-95
This register holds the size and the memory start address of the Periodic TxFIFO

dieptxf1 on page 18-96
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf2 on page 18-97
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf3 on page 18-98
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf4 on page 18-98
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf5 on page 18-99
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf6 on page 18-100
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf7 on page 18-101
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf8 on page 18-101
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf9 on page 18-102
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf10 on page 18-103
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf11 on page 18-104
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf12 on page 18-104
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf13 on page 18-105
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf14 on page 18-106
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf15 on page 18-107
This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

gotgctl

The OTG Control and Status register controls the behavior and reflects the status of the OTG function.

gotgctl Fields

Bit	Name	Description	Access	Reset
20	otgver	Indicates the OTG revision. In OTG Version 1.3. the core supports Data line pulsing and VBus pulsing for SRP. In OTG Version 2.0 the core supports only Data line pulsing for SRP. **Value** **Description** 0x0 OTG Version 1.3. In this version the core supports Data line 0x1 OTG Version 2.0. In this version the core supports only Data line pulsing for SRP	RW	0x0

Bit	Name	Description	Access	Reset
19	bsesvld	Mode: Device only. Indicates the Device mode transceiver status. In OTG mode, you can use this bit to determine IF the device is connected or disconnected. If you do not enable OTG features (such as SRP and HNP), the read reset value will be 1. The vbus assigns the values internally for non-SRP or non-HNP configurations. **Value** **Description** 0x0 B-session is not valid 0x1 B-session is valid	RO	0x0
18	asesvld	Mode: Host only. Indicates the Host mode transceiver status. If you do not enabled OTG features (such as SRP and HNP), the read reset value will be 1.The vbus assigns the values internally for non-SRP or non-HNP configurations. **Value** **Description** 0x0 A-session is not valid 0x1 A-session is valid	RO	0x0
17	dbnctime	Mode: Host only. Indicates the debounce time of a detected connection. **Value** **Description** 0x0 Long debounce time, used FOR physical connections (100 ms + 2.5 s) 0x1 Short debounce time, used FOR soft connections (2.5 s	RO	0x0
16	conidsts	Mode: Host and Device. Indicates the connector ID status on a connect event.This bit is valid only for Host and Device mode. **Value** **Description** 0x0 The DWC_otg core is in A-Device mode 0x1 The otg core is in B-Device mode	RO	0x1

Bit	Name	Description	Access	Reset
11	`devhnpen`	Mode: Device only. The application sets this bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host. **Value** **Description** 0x0 HNP is not enabled in the application 0x1 HNP Enabled	RW	0x0
10	`hstsethnpen`	Mode: Host only. The application sets this bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device. **Value** **Description** 0x0 Host Set HNP is not enabled 0x1 Host Set HNP is enabled	RW	0x0
9	`hnpreq`	Mode: Device only. The application sets this bit to initiate an HNP request to the connected USB host. The application can clear this bit by writing a 0 when the Host Negotiation Success Status Change bit in the OTG Interrupt register (GOTGINT.HstNegSucStsChng) is SET.The core clears this bit when the HstNegSucStsChng bit iscleared. **Value** **Description** 0x0 No HNP request 0x1 HNP request	RW	0x0
8	`hstnegscs`	Mode: Device only. Host Negotiation Success (HstNegScs) The core sets this bit when host negotiation is successful. The core clears this bit when the HNP Request (HNPReq) bit in this register is SET. **Value** **Description** 0x0 Host negotiation failure 0x1 Host negotiation success	RO	0x0

Bit	Name	Description	Access	Reset
7	bvalidovval	This bit is used to set Override value for Bvalid signalwhen GOTGCTL.BvalidOvEn is set. **Value** **Description** 0x0 Bvalid value when GOTGCTL.AvalidOvEn =1 0x1 Bvalid value when GOTGCTL.AvalidOvEn =1	RW	0x0
6	bvalidoven	This bit is used to enable/disable the software to override the Bvalid signal using the GOTGCTL.BvalidOvVal. **Value** **Description** 0x0 Override is disabled and bvalid signal from the respective PHY selected is used internally by the core 0x1 Internally Bvalid received from the PHY is overridden with GOTGCTL.BvalidOvVal	RW	0x0
5	avalidovval	This bit is used to set Override value for Avalid signal when GOTGCTL.BvalidOvEn is set. **Value** **Description** 0x0 Avalid value is 1'b0 when GOTGCTL.BvalidOvEn =1 0x1 Avalid value is 1'b1 when GOTGCTL.BvalidOvEn =1	RW	0x0
4	avalidoven	This bit is used to enable/disable the software to override the Avalid signal using the GOTGCTL.AvalidOvVal. **Value** **Description** 0x0 Override is disabled and Avalid signal from the respective PHY is used internally by the core. 0x1 Internally Avalid received from the PHY is overridden with GOTGCTL.AvalidOvVa	RW	0x0

Bit	Name	Description	Access	Reset
3	`vbvalidovval`	This bit is used to set Override value for vbus valid signal when GOTGCTL.VbvalidOvEn is set. **Value** **Description** 0x0 vbusvalid value when GOTGCTL.VbvalidOvEn = 1 0x1 vbusvalid value when GOTGCTL.VbvalidOvEn is 1	RW	0x0
2	`vbvalidoven`	This bit is used to enable/disable the software to override the vbus-valid signal using the GOTGCTL.vbvalidOvVal.. **Value** **Description** 0x0 Override is disabled and bvalid signal from the respective PHY selected is used internally by the force 0x1 The vbus-valid signal received from the PHY is overridden with GOTGCTL.vbvalidOvVal	RW	0x0
1	`sesreq`	The application sets this bit to initiate a session request on the USB. The application can clear this bit by writing a 0 when the Host Negotiation Success Status Change bit in the OTG Interrupt register (GOTGINT.HstNegSucStsChng) is SET. The core clears this bit when the HstNegSucStsChng bit is cleared. If you use the USB 1.1 Full-Speed Serial Transceiver interface to initiate the session request, the application must wait until the VBUS discharges to 0.2 V, after the B-Session Valid bit in this register (GOTGCTL.BSesVld) is cleared. This discharge time varies between different PHYs and can be obtained from the PHY vendor. **Value** **Description** 0x0 No session request 0x1 Session request	RW	0x0

Bit	Name	Description	Access	Reset
0	sesreqscs	This bit is set when a session request initiation is successful. This bit is valid only For Device Only configuration when OTG_MODE == 3 or OTG_MODE == 4. Applies for device only. **Value** / **Description** 0x0 Session request failure 0x1 Session request success	RO	0x0

gotgint

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

Bit	Name	Description	Access	Reset
19	`dbncedone`	Mode: Host only. The core sets this bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable or SRP Capable bit is SET in the Core USB Configuration register (GUSBCFG.HNPCap or GUSBCFG.SRPCap, respectively). This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — No Change 0x1 — Debounce completed	RO	0x0
18	`adevtoutchg`	Mode:Host and Device. The core sets this bit to indicate that the A-device has timed out WHILE waiting FOR the B-device to connect. This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — No Change 0x1 — A-Device Timeout	RO	0x0
17	`hstnegdet`	Mode:Host and Device. The core sets this bit when it detects a host negotiation request on the USB. This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — No Change 0x1 — Host Negotiation Detected	RO	0x0

Bit	Name	Description	Access	Reset
9	`hstnegsucstschng`	Mode: Host and Device. The core sets this bit on the success or failure of a USB host negotiation request. The application must read the Host Negotiation Success bit of the OTG Control and Status register (GOTGCTL.HstNegScs) to check for success or failure. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Change 0x1 Host Negotiation Status Change	`RO`	`0x0`
8	`sesreqsucstschng`	Mode: Host and Device. The core sets this bit on the success or failure of a session request. The application must read the Session Request Success bit in the OTG Control and Status register (GOTGCTL.SesReqScs) to check for success or failure. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No change 0x1 Session Request Status	`RO`	`0x0`
2	`sesenddet`	Mode:Host and Device.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 Non Active State 0x1 Set when utmisrp_bvalid signal is deasserted	`RO`	`0x0`

gahbcfg

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

Bit	Name	Description	Access	Reset
22	notialldmawrit	This bit is programmed to enable the System DMA Done functionality for all the DMA write Transactions corresponding to the Channel/Endpoint. This bit is valid only when GAHBCFG.RemMemSupp is set to 1. **Value** **Description** 0x1 HSOTG core asserts int_dma_req for all the DMA write transactions on the AHB interface along with int_dma_done, chep_last_transact and chep_number signal informations. The core waits for sys_dma_done signal for all the DMA write transactions in order to complete the transfer of a particular Channel/Endpoint 0x0 HSOTG core asserts int_dma_req signal only for the last transaction of DMA write transfer corresponding to a particular Channel/Endpoint. Similarly, the core waits for sys_dma_done signal only for that transaction of DMA write to complete the transfer of a particular Channel/Endpoint	RW	0x0

Bit	Name	Description	Access	Reset
21	remmemsupp	This bit is programmed to enable/disable the functionality to wait for the system DMA Done Signal for the DMA Write Transfers. -The int_dma_req output signal is asserted when HSOTG DMA starts write transfer to the external memory. When the core is done with the Transfers it asserts int_dma_done signal to flag the completion of DMA writes from HSOTG. The core then waits for sys_dma_done signal from the system to proceed further and complete the Data Transfer corresponding to a particular Channel/Endpoint. -The int_dma_req and int_dma_done signals are not asserted and the core proceeds with the assertion of the XferComp interrupt as soon as wait for the system DMA Done Signal for the DMA Write Transfers the DMA write transfer is done at the HSOTG Core Boundary and it doesn't wait for the sys_dma_done signal to complete the DATA **Value** **Description** 0x0 Disable wait for system DMA Done Signal 0x1 Enable wait for the system DMA Done Signal for the DMA Write Transfers	RW	0x0
8	ptxfemplvl	Mode:Host only. Indicates when the Periodic TxFIFO Empty Interrupt bit in the Core Interrupt register (GINTSTS.PTxFEmp) is triggered. This bit is used only in Slave mode. **Value** **Description** 0x0 GINTSTS.PTxFEmp interrupt indicates that the Periodic TxFIFO is half empty 0x1 GINTSTS.PTxFEmp interrupt indicates that the Periodic TxFIFO is completely empty	RW	0x0

Bit	Name	Description	Access	Reset
7	`nptxfemplvl`	Mode:Host and device. This bit is used only in Slave mode. In host mode and with Shared FIFO with device mode, this bit indicates when the Non-Periodic TxFIFO Empty Interrupt bit in the Core Interrupt register (GINTSTS.NPTxFEmp) is triggered. With dedicated FIFO in device mode, this bit indicates when IN endpoint Transmit FIFO empty interrupt (DIEPINTn.TxFEmp) is triggered. Host mode and with Shared FIFO with device mode: **Value** — **Description** 0x0 — DIEPINTn.TxFEmp interrupt indicates that the IN Endpoint TxFIFO is half empty or DIEPINTn.TxFEmp interrupt indicates that the IN Endpoint TxFIFO is half empty 0x1 — GINTSTS.NPTxFEmp interrupt indicates that the Non-Periodic TxFIFO is completely empty or DIEPINTn.TxFEmp interrupt indicates that the IN Endpoint TxFIFO is completely empty	RW	0x0
5	`dmaen`	Mode:Host and device. Enables switching from DMA mode to slave mode. **Value** — **Description** 0x0 — Core operates in Slave mode 0x1 — Core operates in a DMA mode	RW	0x0
4:1	`hbstlen`	Mode:Host and device. This field is used in Internal DMA modes. **Value** — **Description** 0x0 — 1 word or single 0x1 — 4 word or incr 0x2 — 8 word 0x3 — 16 word or incr4 0x4 — 32 word 0x5 — 64 word or incr8 0x6 — 128 word 0x7 — 256 word or incr16 0x8 — Others reserved	RW	0x0

Bit	Name	Description	Access	Reset
0	`glblintrmsk`	Mode: Host and device. The application uses this bit to mask or unmask the interrupt line assertion to itself. Irrespective of this bits setting, the interrupt status registers are updated by the core. **Value** **Description** 0x0 Mask the interrupt assertion to the application 0x1 Unmask the interrupt assertion to the application.	RW	0x0

gusbcfg Fields

Bit	Name	Description	Access	Reset
31	`corrupttxpkt`	Mode: Host and device. This bit is for debug purposes only. Never Set this bit to 1. The application should always write 0 to this bit. **Value** **Description** 0x0 Normal Mode 0x1 Debug Mode	WO	0x0
30	`forcedevmode`	Mode:Host and device. Writing a 1 to this bit forces the core to device mode. After setting the force bit, the application must wait at least 25 ms before the change to take effect. When the simulation is in scale down mode, waiting for 500 micro-sec is sufficient. **Value** **Description** 0x0 Normal Mode 0x1 Force Device Mode	RW	0x0
29	`forcehstmode`	Mode:Host and device. Writing a 1 to this bit forces the core to host mode After setting the force bit, the application must wait at least 25 ms before the change to take effect. When the simulation is in scale down mode, waiting for 500 micro-sec is sufficient. **Value** **Description** 0x0 Normal Mode 0x1 Force Host Mode	RW	0x0
28	`txenddelay`	Mode: Device only. Set to non UTMI+. **Value** **Description** 0x0 Normal Mode	RW	0x0
25	`ulpi`	Mode:Host only. Controls circuitry built into the PHY for protecting the ULPI interface when the link tri-states STP and data. Any pull-ups or pull-downs employed by this feature can be disabled. **Value** **Description** 0x0 Enables the interface protect circuit 0x1 Disables the interface protect circuit	RW	0x0

Bit	Name	Description	Access	Reset
24	`indicator`	Mode:Host only. Controls wether the Complement Output is qualified with the Internal Vbus Valid comparator before being used in the Vbus State in the RX CMD. **Value** **Description** 0x0 Complement Output signal is qualified with the Internal VbusValid comparator 0x1 Complement Output signal is not qualified with the Internal VbusValid comparator	RW	0x0
23	`complement`	Mode:Host only. Controls the PHY to invert the ExternalVbusIndicator inputsignal, generating the ComplementOutput. Please refer to the ULPI Spec for more detail. **Value** **Description** 0x0 PHY does not invert ExternalVbusIndicator signal 0x1 PHY does invert ExternalVbusIndicator signal	RW	0x0
22	`termseldlpulse`	Mode:Device only. This bit selects utmi_termselect to drive data line pulse during SRP. **Value** **Description** 0x0 Data line pulsing using utmi_txvalid 0x1 Data line pulsing using utmi_termsel	RW	0x0
21	`ulpiextvbusindicator`	Mode:Host only. This bit indicates to the ULPI PHY to use an external VBUS overcurrent indicator. **Value** **Description** 0x0 PHY uses internal VBUS valid comparator 0x1 PHY uses external VBUS valid comparator	RW	0x0
20	`ulpiextvbusdrv`	Mode:Host only. This bit selects between internal or external supply to drive 5V on VBUS, in ULPI PHY. **Value** **Description** 0x0 PHY drives VBUS using internal charge pump 0x1 PHY drives VBUS using external supply	RW	0x0

Bit	Name	Description	Access	Reset
19	`ulpiclksusm`	Mode:Host and Device. This bit sets the ClockSuspendM bit in the Interface Control register on the ULPI PHY. This bit applies only in serial or carkit modes. **Value** **Description** 0x0 PHY powers down internal clock during suspend 0x1 PHY does not power down internal clock	RW	0x0
18	`ulpiautores`	Mode:Host and Device. This bit sets the AutoResume bit in the Interface Control register on the ULPI PHY. **Value** **Description** 0x0 PHY does not use AutoResume feature 0x1 PHY uses AutoResume feature	RW	0x0
13:10	`usbtrdtim`	Mode: Device only. Sets the turnaround time in PHY clocks. Specifies the response time for a MAC request to the Packet FIFO Controller (PFC) to fetch data from the DFIFO (SPRAM). The value is calculated for the minimum AHB frequency of 30 MHz. USB turnaround time is critical for certification where long cables and 5-Hubs are used, so If you need the AHB to run at less than 30 MHz, and If USB turnaround time is not critical, these bits can be programmed to a larger value. **Value** **Description** 0x9 MAC interface is 8-bit UTMI+.	RW	0x5
9	`hnpcap`	Mode:Host and Device. The application uses this bit to control the otg core's HNP capabilities. **Value** **Description** 0x0 HNP capability is not enabled. 0x1 HNP capability is enabled	RW	0x0

Bit	Name	Description	Access	Reset
8	`srpcap`	Mode:Host and Device. The application uses this bit to control the otg core SRP capabilities. If the core operates as a non-SRP-capable B-device, it cannot request the connected A-device (host) to activate VBUS and start a session. This bit is writable only If an SRP mode was specified for Mode of Operation in coreConsultant (parameter OTG_MODE). Otherwise, reads Return 0. **Value** **Description** 0x0 SRP capability is not enabled 0x1 SRP capability is enabled	`RW`	`0x0`
7	`ddrsel`	Mode:Host and Device. The application uses this bit to select a Single Data Rate (SDR) or Double Data Rate (DDR) or ULPI interface. **Value** **Description** 0x0 Single Data Rate ULPI Interfacewith 8-bit-wide data bus 0x1 Double Data Rate ULPI Interface, with 4-bit-wide data bus	`RW`	`0x0`
6	`physel`	Mode:Host and Device. The application uses USB 2.0. **Value** **Description** 0x0 USB 2.0 high-speed ULPI	`RO`	`0x0`
5	`fsintf`	Mode:Host and Device. The application can Set this bit to select between the 3- and 6-pin interfaces, and access is Read and Write. **Value** **Description** 0x0 6-pin unidirectional full-speed serial interface 0x1 3-pin bidirectional full-speed serial interface	`RO`	`0x0`
4	`ulpi_utmi_sel`	Mode:Host and Device. The application uses ULPI Only in 8bit mode. **Value** **Description** 0x0 ULPI PHY	`RO`	`0x1`

Bit	Name	Description	Access	Reset
3	phyif	Mode:Host and Device. This application uses a ULPI interface only. Hence only 8-bit setting is relevant. This setting should not matter since UTMI is not enabled. **Value** — **Description** 0x0 — PHY 8bit Mode	RO	0x0
2:0	toutcal	Mode:Host and Device. The number of PHY clocks that the application programs in this field is added to the high-speed/full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the linestate condition can vary from one PHY to another. The USB standard timeout value for high-speed operation is 736 to 816 (inclusive) bit times. The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock are: High-speed operation: -One 30-MHz PHY clock = 16 bit times -One 60-MHz PHY clock = 8 bit times Full-speed operation: -One 30-MHz PHY clock = 0.4 bit times -One 60-MHz PHY clock = 0.2 bit times -One 48-MHz PHY clock = 0.25 bit times	RW	0x0

grstctl

The application uses this register to reset various hardware features inside the core

grstctl Fields

Bit	Name	Description	Access	Reset
31	ahbidle	Mode:Host and Device. Indicates that the AHB Master State Machine is in the IDLE condition. **Value** — **Description** 0x0 — Not Idle 0x1 — AHB Master Idle	RO	0x1
30	dmareq	Mode:Host and Device. Indicates that the DMA request is in progress. Used for debug. **Value** — **Description** 0x0 — No DMA request 0x1 — DMA request is in progress	RO	0x0

Bit	Name	Description	Access	Reset
10:6	`txfnum`	Mode:Host and Device. This is the FIFO number that must be flushed using the TxFIFO Flush bit. This field must not be changed until the core clears the TxFIFO Flush bit. **Value** **Description** 0x0 - Non-periodic TxFIFO flush in Host mode - Non-periodic TxFIFO flush in device mode when in shared FIFO operation 0x1 - Periodic TxFIFO flush in Host mode - Periodic TxFIFO 1 flush in Device mode when in sharedFIFO operation 0x2 - Periodic TxFIFO 2 flush in Device mode when in sharedFIFO operation- TXFIFO 2 flush in device mode when in dedicated FIFO mode 0xf - Periodic TxFIFO 15 flush in Device mode when in shared FIFO operation - TXFIFO 15 flush in device mode when in dedicated FIFO mode 0x10 Flush all the transmit FIFOs in device or host mode.	`RW`	`0x0`
5	`txfflsh`	Mode:Host and Device. This bit selectively flushes a single or all transmit FIFOs, but cannot do so If the core is in the midst of a transaction. The application must write this bit only after checking that the core is neither writing to the TxFIFO nor reading from the TxFIFO. Verify using these registers: ReadNAK Effective Interrupt ensures the core is notreading from the FIFO WriteGRSTCTL.AHBIdle ensures the core is not writinganything to the FIFO. Flushing is normally recommended when FIFOs are reconfigured or when switching between Shared FIFO and Dedicated Transmit FIFO operation. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower clock of phy_clk or hclk. **Value** **Description** 0x0 No Flush 0x1 selectively flushes a single or all transmit FIFOs	`RO`	`0x0`

Bit	Name	Description	Access	Reset
4	`rxfflsh`	Mode:Host and Device. The application can flush the entire RxFIFO using this bit, but must first ensure that the core is not in the middle of a transaction. The application must only write to this bit after checking that the core is neither reading from the RxFIFO nor writing to the RxFIFO. The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear. **Value** **Description** 0x0 no flush the entire RxFIFO 0x1 flush the entire RxFIFO	`RO`	`0x0`
2	`frmcntrrst`	Mode:Host only. The application writes this bit to reset the (micro)frame number counter inside the core. When the (micro)frame counter is reset, the subsequent SOF sent out by the core has a (micro) frame number of 0. When application writes 1 to the bit, it might not be able to read back the value as it will get cleared by the core in a few clock cycles. **Value** **Description** 0x0 No reset 0x1 Host Frame Counter Reset	`RO`	`0x0`

Bit	Name	Description	Access	Reset
0	csftrst	Mode:Host and Device. Resets the hclk and phy_clock domains as follows:Clears the interrupts and all the CSR registers except the following register bits: - PCGCCTL.RstPdwnModule - PCGCCTL.GateHclk - PCGCCTL.PwrClmp - PCGCCTL.StopPPhyLPwrClkSelclk - GUSBCFG.PhyLPwrClkSel - GUSBCFG.DDRSel - GUSBCFG.PHYSel - GUSBCFG.FSIntf - GUSBCFG.ULPI_UTMI_Sel - GUSBCFG.PHYIf - HCFG.FSLSPclkSel - DCFG.DevSpd - GGPIO - GPWRDN - GADPCTL All module state machines (except the AHB Slave Unit) are reset to the IDLE state, and all the transmit FIFOs and the receive FIFO are flushed. Any transactions on the AHB Master are terminated as soonas possible, after gracefully completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately. When Hibernation or ADP feature is enabled, the PMU module is not reset by the Core Soft Reset.The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit is cleared software must wait at least 3 PHY clocks before doing any access to the PHY domain (synchronization delay). Software must also must check that bit 31 of this register is 1 (AHB Master is IDLE) before starting any operation.Typically software reset is used during software development and also when you dynamically change the PHY selection bits in the USB configuration registers listed above. When you change the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation. **Value** / **Description** 0x0 No reset 0x1 Resets hclk and phy_clock domains	RO	0x0

gintsts

This register interrupts the application for system-level events in the current mode (Device mode or Host mode). Some of the bits in this register are valid only in Host mode, while others are valid in Device mode only. This register also indicates the current mode. To clear the interrupt status bits of type R_SS_WC, the application must write 1 into the bit. The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically. The application must clear the GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

Bit	Name	Description	Access	Reset
22	`fetsusp`	Mode: Device only. This interrupt is valid only in DMA mode. This interrupt indicates that the core has stopped fetching data for IN endpoints due to the unavailability of TxFIFO space or Request Queue space. This interrupt is used by the application for an endpoint mismatch algorithm. for example, after detecting an endpoint mismatch, the application: - Sets a Global non-periodic IN NAK handshake - Disables In endpoints - Flushes the FIFO - Determines the token sequence from the IN Token Sequence Learning Queue - Re-enables the endpoints - Clears the Global non-periodic IN NAK handshake If the Global non-periodic IN NAK is cleared, the core has not yet fetched data for the IN endpoint, and the IN token is received: the core generates an IN token received when FIFO empty interrupt. The OTG Then sends the host a NAK response. To avoid this scenario, the application can check the GINTSTS.FetSusp interrupt, which ensures that the FIFO is full before clearing a Global NAK handshake. Alternatively, the application can mask the "IN token received when FIFO empty" interrupt when clearing a Global IN NAKhandshake. **Value** — **Description** 0x0 — Not active 0x1 — Data Fetch Suspended	RO	0x0
21	`incomplp`	Mode: Device only. In Host mode, the core sets this interrupt bit when there are incomplete periodic transactions still pending which arescheduled for the current microframe. Incomplete Isochronous OUT Transfer (incompISOOUT) The Device mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current microframe. This interrupt is asserted along with the End of Periodic Frame Interrupt (EOPF) bit in this register. This bit can be set only by the core and the application should write 1 to clear it **Value** — **Description** 0x0 — Not active 0x1 — Incomplete Periodic Transfer	RO	0x0

Bit	Name	Description	Access	Reset
20	`incompisoin`	Mode: Device only. The core sets this interrupt to indicate that there is at least isochronous IN endpoint on which the transfer is not completed in the current microframe. This interrupt is asserted along with the End of Periodic Frame Interrupt (EOPF) bit in this register. This interrupt is not asserted in Scatter/Gather DMA mode. **Value** **Description** 0x0 Not active 0x1 Incomplete Isochronous IN Transfer	`RO`	`0x0`
19	`oepint`	Mode: Device only. The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in Device mode). The application must read the Device All Endpoints Interrupt (DAINT) register to determine the exact number of the OUT endpoint on which the interrupt occurred, and Then read the corresponding Device OUT Endpoint-n Interrupt (DOEPINTn) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding DOEPINTn register to clear this bit. **Value** **Description** 0x0 Not active 0x1 OUT Endpoints Interrupt	`RO`	`0x0`
18	`iepint`	Mode: Device only. The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in Device mode). The application must read the Device All Endpoints Interrupt (DAINT) register to determine the exact number of the IN endpoint on Device IN Endpoint-n Interrupt (DIEPINTn) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding DIEPINTn register to clear this bit. **Value** **Description** 0x0 Not active 0x1 IN Endpoints Interrupt	`RO`	`0x0`

Bit	Name	Description	Access	Reset
17	`epmis`	Mode: Device only. This interrupt is valid only in shared FIFO operation. Indicates that an IN token has been received for a non-periodic endpoint, but the data for another endpoint is present in the top of the Non-periodic Transmit FIFO and the IN endpoint mismatch count programmed by the application has expired. **Value** **Description** 0x0 Not active 0x1 Endpoint Mismatch Interrup	RO	0x0
14	`isooutdrop`	Mode: Device only. The core sets this bit when it fails to write an isochronous OUT packet into the RxFIFO because the RxFIFO does not have enough space to accommodate a maximum packet size packet for the isochronous OUT endpoint. **Value** **Description** 0x0 Not active 0x1 Isochronous OUT Packet Dropped Interrup	RO	0x0
13	`enumdone`	Mode: Device only. The core sets this bit to indicate that speed enumeration is complete. The application must read the Device Status register to obtain the enumerated speed. **Value** **Description** 0x0 Not active 0x1 Enumeration Done	RO	0x0
12	`usbrst`	Mode: Device only. The core sets this bit to indicate that a reset is detected on the USB. **Value** **Description** 0x0 Not active 0x1 USB Reset	RO	0x0

Bit	Name	Description	Access	Reset
11	`usbsusp`	Mode: Device only. The core sets this bit to indicate that a suspend was detected on the USB. The core enters the Suspended state when there is no activity on the phy_line_state_i signal for an extended period of time. **Value** **Description** 0x0 Not Active 0x1 USB Suspend	RO	0x0
10	`erlysusp`	Mode: Device only. The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms. **Value** **Description** 0x0 No Idle 0x1 Idle state detecetd	RO	0x0
7	`goutnakeff`	Mode: Device only. Indicates that the Set Global OUT NAK bit in the Device Control register (DCTL.SGOUTNak), Set by the application, has taken effect in the core. This bit can be cleared by writing the Clear Global OUT NAK bit in the Device Control register (DCTL.CGOUTNak). **Value** **Description** 0x0 No Active 0x1 Global OUT NAK Effective	RO	0x0
6	`ginnakeff`	Mode: Device only. Indicates that the Set Global Non-periodic IN NAK bit in the Device Control register (DCTL.SGNPInNak), Set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit Set by the application. This bit can be cleared by clearing the Clear Global Non-periodic IN NAK bit in the Device Control register (DCTL.CGNPInNak). This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit. **Value** **Description** 0x0 Not active 0x1 Set Global Non-periodic IN NAK bi	RO	0x0

Bit	Name	Description	Access	Reset
4	rxflvl	Mode: Host and Device. Indicates that there is at least one packet pending to be read from the RxFIFO. **Value** **Description** 0x0 Not Active 0x1 Rx Fifo Non Empty	RO	0x0
3	sof	Mode: Host and Device. In Host mode, the core sets this bit to indicate that an SOF (FS), micro-SOF (HS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt. In Device mode, the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the Device Status register to get the current (micro)Frame number. This interrupt is seen only when the core is operating at either HS or FS. This bit can be set only by the core and the application should write 1 to clear it. This register may return 1 if read immediately after power on reset. If the register bit reads 1 immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit. **Value** **Description** 0x0 No sof 0x1 Start of Frame	RO	0x0
2	otgint	Mode: Host and Device. The core sets this bit to indicate an OTG protocol event. The application must read the OTG Interrupt Status (GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the GOTGINT register to clear this bit. **Value** **Description** 0x0 No Interrupt 0x1 OTG Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	modemis	Mode: Host and Device. The core sets this bit when the application is trying to access: -A Host mode register, when the core is operating in Device mode. -A Device mode register, when the core is operating in Host mode. The register access is completed on the AHB with an OKAYresponse, but is ignored by the core internally and does not affect the operation of the core. This bit can be set only by the core and the application should write 1 to clearit **Value** — **Description** 0x0 — No Mode Mismatch Interrupt 0x1 — Mode Mismatch Interrupt	RO	0x0
0	curmod	Mode: Host and Device. Indicates the current mode. **Value** — **Description** 0x0 — Device mode 0x1 — Host mode	RO	0x0

gintmsk

This register works with the Interrupt Register (GINTSTS) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the GINTSTS register bit corresponding to that interrupt is still set.

grxstsr

A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the RxFIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.

ghwcfg2 Fields

Bit	Name	Description	Access	Reset
30:26	`tknqdepth`	Range: 0 to 30.	RO	0x8
25:24	`ptxqdepth`	Specifies the Host mode Periodic Request Queue depth.That is, the maximum number of packets that can reside in the Host Periodic TxFIFO. This queue holds one entry corresponding to each IN or OUT periodic request. This queue is 9 bits wide. **Value** — **Description** 0x0 — Que Depth 2 0x1 — Que Depth 4 0x2 — Que Depth 8 0x3 — Que Depth 16	RO	0x0
23:22	`nptxqdepth`	Specifies the Non-periodic Request Queue depth, the maximum number of packets that can reside in the Non-periodic TxFIFO. In Device mode, the queue is used only in Shared FIFO Mode (Enable Dedicated Transmit FIFO for device IN Endpoints? =No). In this mode, there is one entry in the Non-periodic Request Queue for each packet in the Non-periodic TxFIFO. In Host mode, this queue holds one entry corresponding to each IN or OUT nonperiodic request. This queue is seven bits wide. **Value** — **Description** 0x0 — Que size 2 0x1 — Que size 4 0x2 — Que size 8	RO	0x2
20	`multiprocintrpt`	Not implemented. **Value** — **Description** 0x0 — No Multi Processor Interrupt Enabled	RO	0x0
19	`dynfifosizing`	Feature supported. **Value** — **Description** 0x1 — Dynamic FIFO Sizing Enabled	RO	0x1

Bit	Name	Description	Access	Reset
18	`periosupport`	Feature supported. **Value** **Description** 0x1 Periodic OUT Channels Supported in Host Mode Supported	RO	0x1
17:14	`numhstchnl`	Indicates the number of host channels supported by the core in Host mode. **Value** **Description** 0x0 Host Channel 1 0x1 Host Channel 2 0x2 Host Channel 3 0x3 Host Channel 4 0x4 Host Channel 5 0x5 Host Channel 6 0x6 Host Channel 7 0x7 Host Channel 8 0x8 Host Channel 9 0x9 Host Channel 10 0xa Host Channel 11 0xb Host Channel 12 0xc Host Channel 13 0xd Host Channel 14 0xe Host Channel 15 0xf Host Channel 16	RO	0xF

Bit	Name	Description	Access	Reset
13:10	`numdeveps`	The number of endpoints is 1 to 15 in Device mode in addition to control endpoint 0. **Value** **Description** 0x0 End point 0 0x1 End point 1 0x2 End point 2 0x3 End point 3 0x4 End point 4 0x5 End point 5 0x6 End point 6 0x7 End point 7 0x8 End point 8 0x9 End point 9 0xa End point 10 0xb End point 11 0xc End point 12 0xd End point 13 0xe End point 14 0xf End point 15	RO	0xF
9:8	`fsphytype`	Specifies the Full Speed PHY in use. **Value** **Description** 0x2 ULPI Type	RO	0x0
7:6	`hsphytype`	Specifies the High Speed PHY in use. **Value** **Description** 0x0 High-Speed interface not supported 0x2 ULPI	RO	0x2
5	`singpnt`	Single Point Only. **Value** **Description** 0x1 Single-point applicatio	RO	0x0

Bit	Name	Description	Access	Reset

ghwcfg4 Fields

Bit	Name	Description	Access	Reset
31	dma	Enable descriptor based scatter/gather DMA. When enabled, DMA operations will be serviced with descriptor based scatter/gather DMA **Value** **Description** 0x1 Dynamic configuration	RO	0x1
30	dma_configuration	Selects bewteen scatter and nonscatter configuration **Value** **Description** 0x0 Non-Scatter/Gather DMA configuration 0x1 Scatter/Gather DMA configuration	RO	0x1

Bit	Name	Description	Access	Reset
29:26	`ineps`	Number of Device Mode IN Endpoints Including Control. **Value** **Description** 0x0 In Endpoint 1 0x1 In Endpoint 2 0x2 In Endpoint 3 0x3 In Endpoint 4 0x4 In Endpoint 5 0x5 In Endpoint 6 0x6 In Endpoint 7 0x7 In Endpoint 8 0x8 In Endpoint 9 0x9 In Endpoint 10 0xa In Endpoint 11 0xb In Endpoint 12 0xc In Endpoint 13 0xd In Endpoint 14 0xe In Endpoint 15 0xf In Endpoint 16	RO	0xF
25	`dedfifomode`	Specifies whether Dedicated Transmit FIFOs should be enabled in device mode. **Value** **Description** 0x1 Dedicated Transmit FIFO Operation enabled	RO	0x1
24	`sessendfltr`	Specifies whether to add a filter on the session_end input from the PHY. **Value** **Description** 0x0 No filter	RO	0x0
23	`bvalidfltr`	Specifies whether to add a filter on the b_valid input from the PHY. **Value** **Description** 0x0 No Filter	RO	0x0

Bit	Name	Description	Access	Reset
22	`avalidfltr`	Specifies whether to add a filter on the b_valid input from the PHY. **Value** **Description** 0x0 No filter	RO	0x0
21	`vbusvalidfltr`	Vbus Valid Filter Enabled (VBusValidFltr) 0: No filter 1: Filter(coreConsultant parameter: OTG_EN_VBUSVALID_FILTER) **Value** **Description** 0x0 Vbus Valid Filter Disabled	RO	0x0
20	`iddgfltr`	Specifies whether to add a filter on the iddig input from the PHY. This is not relevant since we only support ULPI and there is no iddig pin exposed to I/O pads. **Value** **Description** 0x0 Iddig Filter Disabled	RO	0x0

Bit	Name	Description	Access	Reset
19:16	`numctleps`	Specifies the number of Device mode control endpoints in addition to control endpoint 0, which is always present. Range: 0-15. **Value** **Description** 0x0 End point 0 0x1 End point 1 0x2 End point 2 0x3 End point 3 0x4 End point 4 0x5 End point 5 0x6 End point 6 0x7 End point 7 0x8 End point 8 0x9 End point 9 0xa End point 10 0xb End point 11 0xc End point 12 0xd End point 13 0xe End point 14 0xf End point 15	`RO`	`0xF`
15:14	`phydatawidth`	Uses a ULPI interface only. Hence only 8-bit setting is relevant. This setting should not matter since UTMI is not enabled.	`RO`	`0x0`
6	`hibernation`	Enables power saving mode hibernation. **Value** **Description** 0x0 Hibernation feature disabled	`RO`	`0x0`
5	`ahbfreq`	When the AHB frequency is less than 60 MHz, 4-deep clock-domain crossing sink and source buffers are instantiated between the MAC and the Packet FIFO Controller (PFC); otherwise, two-deep buffers are sufficient. **Value** **Description** 0x1 Minimum AHB Frequency Less Than 60 MH	`RO`	`0x1`

Bit	Name	Description	Access	Reset
4	partialpwrdn	Specifies whether to enable power optimization. **Value** **Description** 0x0 Partial Power Down disabled	RO	0x0
3:0	numdevperioeps	The maximum number of device IN operations is 16 active at any time including endpoint 0, which is always present. This parameter determines the number of device mode Tx FIFOs to be instantiated.	RO	0x0

gdfifocfg

Specifies whether Dedicated Transmit FIFOs should be enabled in device mode.

Module Instance	Base Address	Register Address

Host Mode Registers Register Descriptions

These registers must be programmed every time the USB OTG Controller changes to Host mode.

Offset: 0x400

hcfg on page 18-117
Host Mode control. This register must be programmed every time the core changes to Host mode

hfir on page 18-120
This register stores the frame interval information for the current speed to which the otg core has enumerated

hfnum on page 18-121
This register contains the free space information for the Periodic TxFIFO and the Periodic Transmit Request Queue

hptxsts on page 18-122
This register contains the free space information for the Periodic TxFIFO and the Periodic Transmit Request Queue.

haint on page 18-125
When a significant event occurs on a channel, the Host All Channels Interrupt register interrupts the application using the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt). There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Host Channel-n Interrupt register.

haintmsk on page 18-126
The Host All Channel Interrupt Mask register works with the Host All Channel Interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

hflbaddr on page 18-126
This Register is valid only for Host mode Scatter-Gather DMA. Starting address of the Frame list. This register is used only for Isochronous and Interrupt Channels.

hprt on page 18-127
This register is available only in Host mode. Currently, the OTG Host supports only one port. A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port.The R_SS_WC bits in this register can trigger an interrupt to the application through the Host Port Interrupt bit of the Core Interrupt register (GINTSTS.PrtInt). On a Port Interrupt, the application must read this register and clear the bit that caused the interrupt. for the R_SS_WC bits, the application must write a 1 to the bit to clear the interrupt

hcchar0 on page 18-131
Channel_number: 0.

hcsplt0 on page 18-134
Channel_number 0

hcint0 on page 18-136
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk0 on page 18-140
This register reflects the mask for each channel status described in the previous section.

hctsiz0 on page 18-141
Buffer DMA Mode

hcdma0 on page 18-143
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab0 on page 18-144
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar1 on page 18-145
Host Channel 1 Characteristics Register

hcsplt1 on page 18-148
Channel_number 1

hcint1 on page 18-150
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk1 on page 18-154
This register reflects the mask for each channel status described in the previous section.

hctsiz1 on page 18-155
Buffer DMA Mode

hcdma1 on page 18-157
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab1 on page 18-158
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar2 on page 18-159
Host Channel 2 Characteristics Register

hcsplt2 on page 18-162
Channel_number 2

hcint2 on page 18-164
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk2 on page 18-168
This register reflects the mask for each channel status described in the previous section.

hctsiz2 on page 18-169
Buffer DMA Mode.

hcdma2 on page 18-171
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab2 on page 18-172
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar3 on page 18-173
Channel_number: 3.

hcsplt3 on page 18-176
Channel_number 3

hcint3 on page 18-178
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk3 on page 18-182
This register reflects the mask for each channel status described in the previous section.

hctsiz3 on page 18-183
Buffer DMA Mode

hcdma3 on page 18-185
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab3 on page 18-186
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar4 on page 18-187
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcsplt4 on page 18-187
Channel_number 4

hcint4 on page 18-189
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk4 on page 18-193
This register reflects the mask for Channel 4 interrupt status bits.

hctsiz4 on page 18-195
Buffer DMA Mode Channel 4

hcdma4 on page 18-196
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab4 on page 18-197
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar5 on page 18-198
Channel_number: 5.

hcsplt5 on page 18-202
Channel_number 5

hcint5 on page 18-204
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk5 on page 18-208
This register reflects the mask for each channel status described in the previous section.

hctsiz5 on page 18-209
Buffer DMA Mode

hcdma5 on page 18-211
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab5 on page 18-212
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar6 on page 18-213
Host Channel 6 Characteristics Register

hcsplt6 on page 18-216
Channel_number 6

hcint6 on page 18-218
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk6 on page 18-222
This register reflects the mask for each channel status described in the previous section.

hctsiz6 on page 18-223
Buffer DMA Mode

hcdma6 on page 18-225
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab6 on page 18-226
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. hcchar9 on page 18-255
Host Channel 9 Characteristics Register

hcsplt9 on page 18-258
Channel_number 9

hcint9 on page 18-260
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk9 on page 18-264
This register reflects the mask for each channel status described in the previous section.

hctsiz9 on page 18-265
Buffer DMA Mode

hcdma9 on page 18-267
This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab9 on page 18-268
These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar10 on page 18-269
Host Channel 1 Characteristics Register

hcsplt10 on page 18-272
Channel_number 1

hcint10 on page 18-274
This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk10 on page 18-278

hcfg Fields

Bit	Name	Description	Access	Reset
31	modechtimen	This bit is used to enable or disable the host core to wait for 200 PHY clock cycles at the end of Resume to change the opmode signal to the PHY to 00 after Suspend or LPM. **Value** **Description** 0x0 The Host core waits for either 200 PHY clock cycles or a linestate of SE0 at the end of resume to change the opmode from 0x2 to 0x0 0x1 The Host core waits only for a linestate of SE0 at the end of resume to change the opmode from 0x2 to 0x0	RW	0x0
26	perschedena	Applicable in Scatter/Gather DMA mode only. Enables periodic scheduling within the core. Initially, the bit is reset. The core will not process any periodic channels. As soon as this bit is set, the core will get ready to start scheduling periodic channels. In non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 Disables periodic scheduling within the core 0x1 Enables periodic scheduling within the core	RW	0x0
25:24	frlisten	The value in the register specifies the number of entries in the Frame list. This field is valid only in Scatter/Gather DMA mode. **Value** **Description** 0x0 Reserved 0x1 8 Entries 0x2 16 Entries 0x3 32 Entries	RW	0x0

Bit	Name	Description	Access	Reset
23	descdma	The application can set this bit during initialization to enable the Scatter/Gather DMA operation. This bit must be modified only once after a reset. The following combinations are available for programming: GAHBCFG.DMAEn=0,HCFG.DescDMA=0 => Slave mode GAHBCFG.DMAEn=0,HCFG.DescDMA=1 => InvalidGAHBCFG.DMAEn=1,HCFG.DescDMA=0 => Buffered DMA mode GAHBCFG.DMAEn=1,HCFG.DescDMA=1 => Scatter/Gather DMA mode **Value** **Description** 0x0 No Scatter/Gather DMA 0x1 Scatter/Gather DMA selected	RW	0x0
15:8	resvalid	This field is effective only when HCFG.Ena32KHzS is set. It will control the resume period when the core resumes from suspend. The core counts for ResValid number of clock cycles to detect a valid resume when this is set.	RW	0x2
7	ena32khzs	This bit can only be set if the USB 1.1 Full-Speed Serial Transceiver Interface has been selected. If USB 1.1 Full-Speed Serial Transceiver Interface has not been selected, this bit must be zero. When the USB 1.1 Full-Speed Serial Transceiver Interface is chosen and this bit is set, the core expects the 48-MHz PHY clock to be switched to 32 KHz during a suspend. **Value** **Description** 0x0 USB 1.1 Full-Speed Not Selected 0x1 USB 1.1 Full-Speed Serial Transceiver Interface selected	RW	0x0
2	fslssupp	The application uses this bit to control the core's enumeration speed. Using this bit, the application can make the core enumerate as a FS host, even If the connected device supports HS traffic. Do not make changes to this field after initial programming. **Value** **Description** 0x0 HS/FS/LS, based on the maximum speed supported by the connected device 0x1 FS/LS-only, even if the connected device can support HS	RW	0x0

Bit	Name	Description	Access	Reset
1:0	fslspclksel	When the core is in FS Host mode. The internal PHY clock is running at 30/60 MHZ for ULPI PHY Interfaces. The internal PHY clock is running at 48MHZ for 1.1 FS transceiver Interface When the core is in LS Host mode, the internal PHY clock is running at 30/60 MHZ for ULPI PHY Interfaces. The internal PHY clock is running at 6 MHZ and the external clock is running at 48MHZ. When you select a 6 MHz clock during LS Mode, you must do a soft reset for 1.1 FS transceiver Interface. * When Core in FS mode, the internal and external clocks have the same frequency. * When Core in LS mode, - If fslspclksel is 30/60 Mhz internal and external clocks have the same frequency. - If fslspclksel is 6Mhz the internal clock is divided by eight of external 48 MHz clock (utmifs_clk). **Value** — **Description** 0x0 — PHY clock is running at 30/60 MHz 0x1 — PHY clock is running at 48 MHz 0x2 — PHY clock is running at 6 MHz	RW	0x0

hfir

This register stores the frame interval information for the current speed to which the otg core has enumerated

haint

When a significant event occurs on a channel, the Host All Channels Interrupt register interrupts the application using the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt). There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Host Channel-n Interrupt register.

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset
8	prtrst	When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete. The application must leave this bit Set for at least a minimum duration mentioned below to start a reset on the port. The application can leave it Set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by theUSB standard. This bit is cleared by the core even if there is no device connected to the Host. High speed: 50 ms Full speed/Low speed: 10 ms **Value** — **Description** 0x0 — Port not in reset 0x1 — Port in reset	RW	0x0
7	prtsusp	The application sets this bit to put this port in Suspend mode. The core only stops sending SOFs when this is Set. To stop the PHY clock, the application must Set the Port Clock Stop bit, which asserts the suspend input pin of the PHY. The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wakeup signal is detected or the application sets the Port Reset bit or Port Resume bit in this register or the Resume/Remote Wakeup Detected Interrupt bit or Disconnect Detected Interrupt bit in the Core Interrupt register (GINTSTS.WkUpInt or GINTSTS.DisconnInt, respectively). This bit is cleared by the core even if there is no device connected to the Host. **Value** — **Description** 0x0 — Port not in Suspend mode 0x1 — Port in Suspend mode	RO	0x0

<table>
<tr><th>Bit</th><th>Name</th><th>Description</th><th>Access</th><th>Reset</th></tr>
<tr><td>6</td><td>prtres</td><td>The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit. If the core detects a USB remote wakeup sequence, as indicated by the Port Resume/Remote Wakeup Detected Interrupt bit of the Core Interrupt register (GINTSTS.WkUpInt), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently drivingresume signaling. When LPM is enabled and the core is in the L1 (Sleep) state, setting this bit results in the following behavior: The core continues to drive the resume signal until a pre-determined time specified in the GLPMCFG.HIRD_Thres[3:0] field. If the core detects a USB remote wakeup sequence, as indicated by the Port L1 Resume/Remote L1 Wakeup Detected Interrupt bit of the Core Interrupt register (GINTSTS.L1WkUpInt), the core starts driving resume signaling without application intervention and clears this bit at the end of the resume. The read value of this bit indicates whether the core is currently driving resume signaling.
<table>

hcint0

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma0 Fields

Bit	Name	Description	Access	Reset
31:0	`hcdma0`	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab0

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

Bit	Name	Description	Access	Reset
6:0	prtaddr	This field is the port number of the recipient transactiontranslator.	RW	0x0

hcint1

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** / **Description** 0x0 No Descriptor rollover interrupt 0x1 Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	`xcs_xact_err`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Excessive Transaction Error 0x1 Excessive Transaction Error	RO	0x0
11	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No BNA Interrupt 0x1 BNA Interrupt	RO	0x0
10	`datatglerr`	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 No Data Toggle Error 0x1 Data Toggle Error	RO	0x0
9	`frmovrun`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Frame Overrun 0x1 Frame Overrun	RO	0x0

Bit	Name	Description	Access	Reset
8	`bblerr`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0
7	`xacterr`	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	`nyet`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	`ack`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0

Bit	Name	Description	Access	Reset
4	`nak`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	RO	0x0
3	`stall`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	RO	0x0
2	`ahberr`	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	RO	0x0
1	`chhltd`	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

hcintmsk1

This register reflects the mask for each channel status described in the previous section.

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** — **Description** 0x0 — No ping protocol 0x1 — Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** — **Description** 0x0 — DATA0 0x1 — DATA2 0x2 — DATA1 0x3 — MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	`xfersize`	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma1

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma1 Fields

Bit	Name	Description	Access	Reset
31:0	`hcdma1`	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab1

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcdma2 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma2	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab2

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint3

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint4

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint4 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Descriptor rollover interrupt 0x1 Descriptor rollover interrupt	RO	0x0
12	xcs_xact_err	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Excessive Transaction Error 0x1 Excessive Transaction Error	RO	0x0

Bit	Name	Description	Access	Reset
11	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No BNA Interrupt 0x1 BNA Interrupt	RO	0x0
10	`datatglerr`	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 No Data Toggle Error 0x1 Data Toggle Error	RO	0x0
9	`frmovrun`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Frame Overrun 0x1 Frame Overrun	RO	0x0
8	`bblerr`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0

Bit	Name	Description	Access	Reset
7	xacterr	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	nyet	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	ack	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0
4	nak	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
3	`stall`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	`RO`	`0x0`
2	`ahberr`	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	`RO`	`0x0`
1	`chhltd`	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	`RO`	`0x0`
0	`xfercompl`	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	`RO`	`0x0`

hcintmsk4

This register reflects the mask for Channel 4 interrupt status bits.

hctsiz4 Fields

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** **Description** 0x0 No ping protocol 0x1 Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma4

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma4 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma4	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab4

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcdma5 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma5	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab5

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint6

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab6

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint7

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint7 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** / **Description** 0x0 No Descriptor rollover interrupt 0x1 Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	`xcs_xact_err`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** / **Description** 0x0 No Excessive Transaction Error 0x1 Excessive Transaction Error	RO	0x0
11	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** / **Description** 0x0 No BNA Interrupt 0x1 BNA Interrupt	RO	0x0
10	`datatglerr`	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** / **Description** 0x0 No Data Toggle Error 0x1 Data Toggle Error	RO	0x0
9	`frmovrun`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** / **Description** 0x0 No Frame Overrun 0x1 Frame Overrun	RO	0x0

Bit	Name	Description	Access	Reset
8	`bblerr`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0
7	`xacterr`	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	`nyet`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	`ack`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0

Bit	Name	Description	Access	Reset
4	nak	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	RO	0x0
3	stall	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	RO	0x0
2	ahberr	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	RO	0x0
1	chhltd	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

hcintmsk7

hctsiz7 Fields

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** **Description** 0x0 No ping protocol 0x1 Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	`xfersize`	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	`RW`	`0x0`

hcdma7

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcint8

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint8 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — No Descriptor rollover interrupt 0x1 — Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	`xcs_xact_err`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No Excessive Transaction Error 0x1 Excessive Transaction Error	`RO`	`0x0`
11	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 No BNA Interrupt 0x1 BNA Interrupt	`RO`	`0x0`
10	`datatglerr`	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 No Data Toggle Error 0x1 Data Toggle Error	`RO`	`0x0`
9	`frmovrun`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Frame Overrun 0x1 Frame Overrun	`RO`	`0x0`

Bit	Name	Description	Access	Reset
8	bblerr	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** / **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0
7	xacterr	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** / **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	nyet	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** / **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	ack	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** / **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0

Bit	Name	Description	Access	Reset
4	`nak`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	`RO`	`0x0`
3	`stall`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	`RO`	`0x0`
2	`ahberr`	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	`RO`	`0x0`
1	`chhltd`	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	`RO`	`0x0`

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

hcintmsk8

This register reflects the mask for each channel status described in the previous section.

hctsiz8 Fields

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** **Description** 0x0 No ping protocol 0x1 Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	`xfersize`	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	`RW`	`0x0`

hcdma8

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma8 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma8	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab8

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** **Description** 0x0 No ping protocol 0x1 Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma9

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma9 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma9	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab9

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint10

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint11

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint11 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — No Descriptor rollover interrupt 0x1 — Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	`xcs_xact_err`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — No Excessive Transaction Error 0x1 — Excessive Transaction Error	RO	0x0
11	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — No BNA Interrupt 0x1 — BNA Interrupt	RO	0x0
10	`datatglerr`	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** — **Description** 0x0 — No Data Toggle Error 0x1 — Data Toggle Error	RO	0x0
9	`frmovrun`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — No Frame Overrun 0x1 — Frame Overrun	RO	0x0

Bit	Name	Description	Access	Reset
8	bblerr	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — No Babble Error 0x1 — Babble Error	RO	0x0
7	xacterr	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — No Transaction Error 0x1 — Transaction Error	RO	0x0
6	nyet	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — No NYET Response Received Interrupt 0x1 — NYET Response Received Interrupt	RO	0x0
5	ack	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — No ACK Response Received Transmitted Interrupt 0x1 — ACK Response Received Transmitted Interrup	RO	0x0

Bit	Name	Description	Access	Reset
4	nak	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No NAK Response Received Interrupt 0x1 NAK Response Received Interrupt	RO	0x0
3	stall	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No Stall Interrupt 0x1 Stall Interrupt	RO	0x0
2	ahberr	This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 No AHB error 0x1 AHB error during AHB read/write	RO	0x0
1	chhltd	In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. In Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 Channel not halted 0x1 Channel Halted	RO	0x0

Bit	Name	Description	Access	Reset
0	`xfercompl`	Transfer completed normally without any errors. This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 No transfer 0x1 Transfer completed normally without any errors	RO	0x0

hcintmsk11

This register reflects the mask for each channel status described in the previous section.

hctsiz11 Fields

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** **Description** 0x0 No ping protocol 0x1 Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	`xfersize`	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma11

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma11 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma11	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab11

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcdma12 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma12	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab12

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint13

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint14

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcint14 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. for non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — No Descriptor rollover interrupt 0x1 — Descriptor rollover interrupt	RO	0x0

Bit	Name	Description	Access	Reset
12	`xcs_xact_err`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels.for non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — No Excessive Transaction Error 0x1 — Excessive Transaction Error	RO	0x0
11	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. for non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — No BNA Interrupt 0x1 — BNA Interrupt	RO	0x0
10	`datatglerr`	This bit can be set only by the core and the application should write 1 to clear it. In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** — **Description** 0x0 — No Data Toggle Error 0x1 — Data Toggle Error	RO	0x0
9	`frmovrun`	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — No Frame Overrun 0x1 — Frame Overrun	RO	0x0

Bit	Name	Description	Access	Reset
8	bblerr	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** / **Description** 0x0 No Babble Error 0x1 Babble Error	RO	0x0
7	xacterr	Indicates one of the following errors occurred on the USB.-CRC check failure -Timeout -Bit stuff error -False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** / **Description** 0x0 No Transaction Error 0x1 Transaction Error	RO	0x0
6	nyet	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** / **Description** 0x0 No NYET Response Received Interrupt 0x1 NYET Response Received Interrupt	RO	0x0
5	ack	In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. This bit can be set only by the core and the application should write 1 to clear it. **Value** / **Description** 0x0 No ACK Response Received Transmitted Interrupt 0x1 ACK Response Received Transmitted Interrup	RO	0x0

hctsiz14 Fields

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** **Description** 0x0 No ping protocol 0x1 Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	`xfersize`	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic). The width of this counter is specified as 19 bits.	`RW`	`0x0`

hcdma14

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma14 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma14	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab14

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint15

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hctsiz15 Fields

Bit	Name	Description	Access	Reset
31	dopng	This bit is used only for OUT transfers.Setting this field to 1 directs the host to do PING protocol. Do not Set this bit for IN transfers. If this bit is set for IN transfers it disables the channel. **Value** **Description** 0x0 No ping protocol 0x1 Ping protocol	RW	0x0
30:29	pid	The application programs this field with the type of PID to use forthe initial transaction. The host maintains this field for the rest of the transfer. **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA (non-control)/SETUP (control)	RW	0x0
28:19	pktcnt	This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.	RW	0x0

Bit	Name	Description	Access	Reset
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma15

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma15 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma15	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab15

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcdmab15 Fields

Bit	Name	Description	Access	Reset
31:0	hcdmab15	These registers are present only in case of Scatter/ Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.	RW	0x0

Device Mode Registers Register Descriptions

These registers must be programmed every time the USB OTG Controller changes to Device mode.

Offset: 0x800

dcfg on page 18-369
This register configures the core in Device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

dctl on page 18-372

dsts on page 18-377
This register indicates the status of the core with respect to USB-related events. It must be read on interrupts from Device All Interrupts (DAINT) register.

diepmsk on page 18-379
This register works with each of the Device IN Endpoint Interrupt (DIEPINTn) registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the DIEPINTn register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

doepmsk on page 18-381
This register works with each of the Device OUT Endpoint Interrupt (DOEPINTn) registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the DOEPINTn register can be masked by writing into the corresponding bit in this register. Status bits are masked by default

daint on page 18-383
When a significant event occurs on an endpoint, a Device All Endpoints Interrupt register interrupts the application using the Device OUT Endpoints Interrupt bit or Device IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively). This is shown in Figure 5-2. There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. for a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint-n Interrupt register (DIEPINTn/DOEPINTn).

daintmsk on page 18-389
The Device Endpoint Interrupt Mask register works with the Device Endpoint Interrupt register to interrupt the application when an event occurs on a device endpoint. However, the Device All Endpoints Interrupt (DAINT) register bit corresponding to that interrupt is still set.

dvbusdis on page 18-394
This register specifies the VBUS discharge time after VBUS pulsing during SRP.

dvbuspulse on page 18-395
This register specifies the VBUS pulsing time during SRP.

dthrctl on page 18-395
Thresholding is not supported in Slave mode and so this register must not be programmed in Slave mode. for threshold support, the AHB must be run at 60 MHz or higher.

diepempmsk on page 18-398
This register is used to control the IN endpoint FIFO empty interrupt generation (DIEPINTn.TxfEmp).

diepctl0 on page 18-401
This register covers Device Control IN Endpoint 0.

diepint0 on page 18-404
This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz0 on page 18-408
The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/ DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

diepdma0 on page 18-409
DMA Addressing.

dtxfsts0 on page 18-410
This register contains the free space information for the Device IN endpoint TxFIFO.

diepdmab0 on page 18-410
Endpoint 16.

diepctl1 on page 18-411
Endpoint_number: 1

diepint1 on page 18-417
This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz1 on page 18-421
The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma1 on page 18-422
DMA Addressing.

dtxfsts1 on page 18-423
This register contains the free space information for the Device IN endpoint TxFIFO.

diepdmab1 on page 18-424
DMA Buffer Address.

diepctl2 on page 18-424
Endpoint_number: 2

diepint2 on page 18-430
This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz2 on page 18-434
The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma2 on page 18-435
DMA Addressing.

DTXFSTS2 on page 18-436
This register contains the free space information for the Device IN endpoint TxFIFO.

diepdmab2 on page 18-437
DMA Buffer Address.

diepctl3 on page 18-437
Endpoint_number: 3

diepint3 on page 18-443
This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz3 on page 18-447
The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma3 on page 18-448
DMA Addressing.

dtxfsts3 on page 18-449
This register contains the free space information for the Device IN endpoint TxFIFO.

diepdmab3 on page 18-450
DMA Buffer Address.

diepctl4 on page 18-450
Endpoint_number: 4

diepint4 on page 18-456
This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz4 on page 18-460
The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma4 on page 18-461
DMA Addressing.

dtxfsts4 on page 18-462
This register contains the free space information for the Device IN endpoint TxFIFO.

diepdmab4 on page 18-463
DMA Buffer Address.

diepctl5 on page 18-463
Endpoint_number: 5

diepint5 on page 18-469
This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz5 on page 18-473
The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepctl10 on page 18-528
Endpoint_number: 10

diepint10 on page 18-534
This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz10 on page 18-538
The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Bit	Name	Description	Access	Reset
13	`endevoutnak`	This bit enables setting NAK for Bulk OUT endpoints after the transfer is completed for Device mode Descriptor DMA It is one time programmable after reset like any other DCFG register bits. **Value** — **Description** 0x0 — The core does not set NAK after Bulk OUT transfer complete 0x1 — The core sets NAK after Bulk OUT transfer complete	RW	0x0
12:11	`perfrint`	Indicates the time within a (micro)frame at which the application must be notified using the End Of Periodic Frame Interrupt. This can be used to determine If all the isochronous traffic for that (micro)frame is complete. 0x0: 80% of the (micro) frame interval 0x1: 85% 0x2: 90% 0x3: 95% **Value** — **Description** 0x0 — 80% of the (micro)frame interval 0x1 — 85% of the (micro)frame interval 0x2 — 90% of the (micro)frame interval 0x3 — 95% of the (micro)frame interval	RW	0x0
10:4	`devaddr`	The application must program this field after every SetAddress control command.	RW	0x0
3	`ena32khzsusp`	When the USB 1.1 Full-Speed Serial Transceiver Interface is chosen and this bit is set, the core expects the 48-MHz PHY clock to be switched to 32 KHz during a suspend. This bit can only be set if USB 1.1 Full-Speed Serial Transceiver Interface has been selected. If USB 1.1 Full-Speed Serial Transceiver Interface has not been selected, this bit must be zero. **Value** — **Description** 0x0 — USB 1.1 Full-Speed Serial Transceiver not selected 0x1 — USB 1.1 Full-Speed Serial Transceiver Interface selected	RW	0x0

Bit	Name	Description	Access	Reset
2	nzstsouthshk	The application can use this field to select the handshake the core sends on receiving a nonzero-length data packet during the OUT transaction of a control transfer's Status stage. 1: Send a STALL handshake on a nonzero-length statusOUT transaction and do not send the received OUT packet tothe application. 0: Send the received OUT packet to the application (zerolengthor nonzero-length) and send a handshake based onthe NAK and STALL bits for the endpoint in the DeviceEndpoint Control register. **Value** / **Description** 0x0 Send the received OUT packet to the application zerolength 0x1 Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application	RW	0x0
1:0	devspd	Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected. **Value** / **Description** 0x0 High speed USB 2.0 PHY clock is 30 MHz or 60 MHz 0x1 Full speed USB 2.0 PHY clock is 30 MHz or 60 MHz 0x2 Low speed USB 1.1 transceiver clock is 6 MHz 0x3 Full speed USB 1.1 transceiver clock is 48 MHz	RW	0x0

Bit	Name	Description	Access	Reset
16	nakonbble	Set NAK automatically on babble (NakOnBble). The core sets NAK automatically for the endpoint on which babble is received. **Value** **Description** 0x0 Disable NAK on Babble Error 0x1 NAK on Babble Error	RW	0x0

Bit	Name	Description	Access	Reset
15	ignrfrmnum	Do NOT program IgnrFrmNum bit to 1'b1 when the core is operating in threshold mode. When Scatter/ Gather DMA mode is enabled this feature is not applicable to High Speed, High bandwidth transfers. When this bit is enabled, there must be only one packet per descriptor. In Scatter/Gather DMA mode, if this bit is enabled, the packets are not flushed when a ISOC IN token is received for an elapsed frame. When Scatter/Gather DMA mode is disabled, this field is used by the application to enable periodic transfer interrupt. The application can program periodic endpoint transfers for multiple (micro) frames. 0: periodic transfer interrupt feature is disabled, application needs to program transfers for periodic endpoints every (micro)frame 1: periodic transfer interrupt feature is enabled, application can program transfers for multiple (micro)frames for periodic endpoints. In non Scatter/Gather DMA mode the application will receive transfer complete interrupt after transfers for multiple (micro)frames are completed. **Value** **Description** 0x0 The core transmits the packets only in the frame number in which they are intended to be transmitted 0x1 The core ignores the frame number, sending packets immediately as the packets are ready	RW	0x0
14:13	gmc	GMC must be programmed only once after initialization.Applicable only for Scatter/Gather DMA mode. This indicates the number of packets to be serviced for that end point before moving to the next end point. It is only for non-periodic end points. When Scatter/Gather DMA mode is disabled, this field isreserved. and reads 0. **Value** **Description** 0x0 Invalid 0x1 1 packet 0x2 2 packets 0x3 3 packets	RW	0x0

Bit	Name	Description	Access	Reset
11	pwronprgdone	The application uses this bit to indicate that register-programming is completed after a wake-up from Power Downmode. **Value** — **Description** 0x0 — Power-On Programming not done 0x1 — Power-On Programming Done	RW	0x0
10	cgoutnak	A write to this field clears the Global OUT NAK. **Value** — **Description** 0x0 — Disable Clear Global OUT NAK 0x1 — Clear Global OUT NAK	WO	0x0
9	sgoutnak	A write to this field sets the Global OUT NAK.The application uses this bit to send a NAK handshake on all OUT endpoints. The application must Set the this bit only after making sure that the Global OUT NAK Effective bit in the Core Interrupt Register GINTSTS.GOUTNakEff) is cleared. **Value** — **Description** 0x0 — Disable Global OUT NAK 0x1 — Global OUT NAK	WO	0x0
8	CGNPInNak	A write to this field clears the Global Non-periodic IN NAK. **Value** — **Description** 0x0 — Disable Global Non-periodic IN NAK 0x1 — Clear Global Non-periodic IN NAK	WO	0x0

Bit	Name	Description	Access	Reset
7	`sgnpinnak`	A write to this field sets the Global Non-periodic IN NAK. The application uses this bit to send a NAK handshake on all nonperiodic IN endpoints. The core can also Set this bit when a timeout condition is detected on a non-periodic endpoint in shared FIFO operation. The application must Set this bit only after making sure that the Global IN NAK Effective bit in the Core Interrupt Register (GINTSTS.GINNakEff) is cleared **Value** **Description** 0x0 Disable Global Non-periodic IN NAK 0x1 Global Non-periodic IN NAK	`WO`	`0x0`
6:4	`tstctl`	Others: Reserved. **Value** **Description** 0x0 Test mode disabled 0x1 Test_J mode 0x2 Test_K mode 0x3 Test_SE0_NAK mode 0x4 Test_Packet mode 0x5 Test_force_Enable	`RW`	`0x0`
3	`goutnaksts`	Reports NAK status. All isochronous OUT packets aredropped. **Value** **Description** 0x0 A handshake is sent based on the FIFO Status and the NAK and STALL bit settings. 0x1 No data is written to the RxFIFO, irrespective of space availability. Sends a NAK handshake on all packets, except on SETUP transactions. All isochronous OUT packets are dropped.	`RO`	`0x0`
2	`gnpinnaksts`	Defines IN NAK conditions. **Value** **Description** 0x0 A handshake is sent out based on the data availability in the transmit FIFO 0x1 A NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO.	`RO`	`0x0`

Bit	Name	Description	Access	Reset
1	sftdiscon	The application uses this bit to signal the otg core to do a soft disconnect. As long as this bit is Set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit. There is a minimum duration for which the core must keep this bit set. When this bit is cleared after a soft disconnect, the core drives the phy_opmode_o signal on the ULPI, which generates a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration.; **Value** — **Description** 0x0 — Normal operation 0x1 — The core drives the phy_opmode_o signal on the ULPI	RW	0x0
0	rmtwkupsig	When the application sets this bit, the core initiates remote signaling to wake up the USB host. The application must Set this bit to instruct the core to exit the Suspend state. As specified in the USB 2.0 specification, the application must clear this bit 115 ms after setting it. Remote Wakeup Signaling (RmtWkUpSig) When LPM is enabled, In L1 state the behavior of this bit is as follows: When the application sets this bit, the core initiates L1 remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the Sleep state. As specified in the LPM specification, the hardware will automatically clear this bit after a time of 50us (TL1DevDrvResume) after set by application. Application should not set this bit when GLPMCFG bRemoteWake from the previous LPM transaction was zero. **Value** — **Description** 0x0 — No exit suspend state 0x1 — Exit Suspend State	RW	0x0

dsts

This register indicates the status of the core with respect to USB-related events. It must be read on interrupts from Device All Interrupts (DAINT) register.

dsts Fields

Bit	Name	Description	Access	Reset
21:8	soffn	When the core is operating at high speed, this field contains a microframe number. When the core is operating at full or low speed, this field contains a Frame number.	RO	0x0
3	errticerr	The core sets this bit to report any erratic errors (phy_rxvalid_i/phy_rxvldh_i or phy_rxactive_i is asserted for at least 2 ms, due to PHY error) seen on the UTMI+ . Due to erratic errors, the otg core goes into Suspended state and an interrupt is generated to the application with Early Suspend bit of the Core Interrupt register (GINTSTS.ErlySusp). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover. **Value** **Description** 0x0 No Erratic Error 0x1 Erratic Error	RO	0x0

Bit	Name	Description	Access	Reset
2:1	`enumspd`	Indicates the speed at which the otg core has come up after speed detection through a chirp sequence. **Value** **Description** 0x0 High speed (PHY clock is running at 30 or 60 MHz) 0x1 Full speed (PHY clock is running at 30 or 60 MHz) 0x2 Low speed (PHY clock is running at 6 MHz) 0x3 Full speed (PHY clock is running at 48 MHz)	`RO`	`0x1`
0	`suspsts`	In Device mode, this bit is Set as long as a Suspend condition is detected on the USB. The core enters the Suspended state when there is no activity on the phy_line_state_i signal for an extended period of time. The core comes out of the suspend: -When there is any activity on the phy_line_state_i signal -When the application writes to the Remote Wakeup Signaling bit in the Device Control register (DCTL.RmtWkUpSig). **Value** **Description** 0x0 No suspend state 0x1 Suspend state	`RO`	`0x0`

diepmsk

This register works with each of the Device IN Endpoint Interrupt (DIEPINTn) registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the DIEPINTn register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

daint

When a significant event occurs on an endpoint, a Device All Endpoints Interrupt register interrupts the application using the Device OUT Endpoints Interrupt bit or Device IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively). This is shown in Figure 5-2.

There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. for a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint-n Interrupt register (DIEPINTn/DOEPINTn).

dthrctl Fields

Bit	Name	Description	Access	Reset
27	arbprken	This bit controls internal DMA arbiter parking for IN endpoints. When thresholding is enabled and this bit is Set to one, Then the arbiter parks on the IN endpoint for which there is a token received on the USB. This is done to avoid getting into underrun conditions. By Default the parking is enabled. **Value** **Description** 0x0 Disable DMA arbiter parking 0x1 Enable DMA arbiter parking for IN endpoints	RW	0x1
25:17	rxthrlen	This field specifies Receive thresholding size in DWORDS.This field also specifies the amount of data received on the USB before the core can start transmitting on the AHB. The threshold length has to be at least eight DWORDS. The recommended value for ThrLen is to be the same as the programmed AHB Burst Length (GAHBCFG.HBstLen).	RW	0x8
16	rxthren	When this bit is Set, the core enables thresholding in the receive direction. **Value** **Description** 0x0 Disable thresholding 0x1 Enable thresholding in the receive direction	RW	0x0

Bit	Name	Description	Access	Reset
12:11	`ahbthrratio`	These bits define the ratio between the AHB threshold and the MAC threshold for the transmit path only. The AHB threshold always remains less than or equal to the USB threshold, because this does not increase overhead. Both the AHB and the MAC threshold must be DWORD-aligned. The application needs to program TxThrLen and the AHBThrRatio to make the AHB Threshold value DWORD aligned. If the AHB threshold value is not DWORD aligned, the core might not behave correctly. When programming the TxThrLen and AHBThrRatio, the application must ensure that the minimum AHB threshold value does not go below 8 DWORDS to meet the USB turnaround time requirements. **Value** **Description** 0x0 AHB threshold = MAC threshold 0x1 AHB threshold = MAC threshold /2 0x2 AHB threshold = MAC threshold /4 0x3 AHB threshold = MAC threshold /	`RW`	`0x0`
10:2	`txthrlen`	This field specifies Transmit thresholding size in DWORDS. This also forms the MAC threshold and specifies the amount of data in bytes to be in the corresponding endpoint transmit FIFO, before the core can start transmit on the USB. The threshold length has to be at least eight DWORDS when the value of AHBThrRatio is 0. In case the AHBThrRatio is non zero the application needs to ensure that the AHB Threshold value does not go below the recommended eight DWORD. This field controls both isochronous and non-isochronous IN endpoint thresholds. The recommended value for ThrLen is to be the same as the programmed AHB Burst Length (GAHBCFG.HBstLen).	`RW`	`0x8`
1	`isothren`	When this bit is Set, the core enables thresholding for isochronous IN endpoints. **Value** **Description** 0x0 No thresholding 0x1 Enables thresholding	`RW`	`0x0`

Bit	Name	Description	Access	Reset
0	nonisothren	When this bit is Set, the core enables thresholding for Non Isochronous IN endpoints. **Value** **Description** 0x0 No thresholding 0x1 Enable thresholding	RW	0x0

diepempmsk

This register is used to control the IN endpoint FIFO empty interrupt generation (DIEPINTn.TxfEmp).

Bit	Name	Description	Access	Reset
25:22	`txfnum`	for Shared FIFO operation, this value is always Set to 0, indicating that control IN endpoint 0 data is always written in the Non-Periodic Transmit FIFO. for Dedicated FIFO operation, this value is Set to the FIFO number that is assigned to IN Endpoint 0.	RW	0x0
21	`stall`	The application can only Set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Nonperiodic IN NAK, or Global OUT NAK is Set along with this bit, the STALL bit takes priority. **Value** — **Description** 0x0 — No Stall 0x1 — Stall Handshake	RO	0x0
19:18	`eptype`	Hardcoded to 00 for control. **Value** — **Description** 0x0 — Endpoint Control 0	RO	0x0
17	`naksts`	When this bit is Set, either by the application or core, the core stops transmitting data, even If there is data available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
15	`usbactep`	This bit is always SET to 1, indicating that control endpoint 0 is always active in all configurations and interfaces. **Value** — **Description** 0x1 — Control endpoint is always active	RO	0x1

Bit	Name	Description	Access	Reset
1:0	mps	Applies to IN and OUT endpoints.The application must program this field with the maximum packet size for the current logical endpoint. **Value** **Description** 0x0 64 bytes 0x1 32 bytes 0x2 16 bytes 0x3 8 bytes	RW	0x0

diepint0

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
9	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	`txfifoundrn`	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	`txfemp`	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	`inepnakeff`	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	`intknepmis`	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	`intkntxfemp`	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	`timeout`	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	`epdisbld`	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	`RO`	`0x0`
0	`xfercompl`	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	`RO`	`0x0`

dieptsiz0

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/ DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

diepdma0 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma0	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/ Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfsts0

This register contains the free space information for the Device IN endpoint TxFIFO.

diepctl1 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/ Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/ Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** / **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** / **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0

Bit	Name	Description	Access	Reset
29	`setd1pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	`WO`	`0x0`
28	`setd0pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Endpoint Data PID to DATA0)	`WO`	`0x0`
27	`snak`	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	`WO`	`0x0`

Bit	Name	Description	Access	Reset
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	WO	0x0
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	RO	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint1

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint1 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0

Bit	Name	Description	Access	Reset
7	`txfemp`	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** — **Description** 0x0 — No interrupt 0x1 — Transmit FIFO Empty interrupt	RO	0x1
6	`inepnakeff`	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** — **Description** 0x0 — No interrupt 0x1 — IN Endpoint NAK Effective interrupt	RO	0x0
5	`intknepmis`	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** — **Description** 0x0 — No interrupt 0x1 — IN Token Received with EP Mismatch interrupt	RO	0x0

Bit	Name	Description	Access	Reset
4	`intkntxfemp`	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	`timeout`	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	`epdisbld`	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/ Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz1

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz1 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** – **Description** 0x1 – 1 packet 0x2 – 2 packets 0x3 – 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

25:22	`txfnum`	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	`RW`	`0x0`
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	`RO`	`0x0`
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	`RW`	`0x0`

Bit	Name	Description	Access	Reset
17	`naksts`	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	`dpid`	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — Not Active 0x1 — USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint2

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint2 Fields

Bit	Name	Description	Access	Reset
14	`nyetintrpt`	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	`nakintrpt`	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	`bbleerr`	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	`pktdrpsts`	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	`intknepmis`	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	`RO`	`0x0`
4	`intkntxfemp`	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	`RO`	`0x0`
3	`timeout`	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	`RO`	`0x0`
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	`RO`	`0x0`

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/ Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz2

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepctl3 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	`epdis`	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** / **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	`RO`	`0x0`
29	`setd1pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** / **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	`WO`	`0x0`

Bit	Name	Description	Access	Reset
28	`setd0pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	`WO`	`0x0`
27	`snak`	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	`WO`	`0x0`
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	`WO`	`0x0`

Bit	Name	Description	Access	Reset
25:22	`txfnum`	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	RO	0x0
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint3

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** — **Description** 0x0 — No interrupt 0x1 — IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	`intknepmis`	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	`intkntxfemp`	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	`timeout`	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — No Interrupt 0x1 — Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** — **Description** 0x0 — No Interrupt 0x1 — Transfer Completed Interrupt	RO	0x0

dieptsiz3

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepctl4 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/ Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/ Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** / **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** / **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** / **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** / **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** / **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** / **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0

<table>
<tr><th>Bit</th><th>Name</th><th>Description</th><th>Access</th><th>Reset</th></tr>
<tr><td>25:22</td><td>txfnum</td><td>Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.</td><td>RW</td><td>0x0</td></tr>
<tr><td>21</td><td>stall</td><td>Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit	Name	Description	Access	Reset
17	`naksts`	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	`dpid`	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint4

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — No interrupt 0x1 — BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** — **Description** 0x0 — No interrupt 0x1 — Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** — **Description** 0x0 — No interrupt 0x1 — IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	`intknepmis`	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** / **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	`intkntxfemp`	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** / **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	`timeout`	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** / **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** / **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	`epdisbld`	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — No Interrupt 0x1 — Endpoint Disabled Interrupt	RO	0x0
0	`xfercompl`	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** — **Description** 0x0 — No Interrupt 0x1 — Transfer Completed Interrupt	RO	0x0

dieptsiz4

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint5

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	`intknepmis`	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	`intkntxfemp`	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	`timeout`	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz5

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** / **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint6

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	`intknepmis`	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** / **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	`intkntxfemp`	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** / **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	`timeout`	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** / **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** / **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz6

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz6 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** **Description** 0x1 1 packet 0x2 2 packets 0x3 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepctl7 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** / **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	`epdis`	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — No Endpoint Disable 0x1 — Endpoint Disable	`RO`	`0x0`
29	`setd1pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	`WO`	`0x0`

Bit	Name	Description	Access	Reset
28	`setd0pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Endpoint Data PID to DATA0)	`WO`	`0x0`
27	`snak`	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	`WO`	`0x0`
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	`WO`	`0x0`

Bit	Name	Description	Access	Reset
25:22	`txfnum`	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	`RW`	`0x0`
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	`RO`	`0x0`
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	`RW`	`0x0`

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — Not Active 0x1 — USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint7

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
5	`intknepmis`	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	`RO`	`0x0`
4	`intkntxfemp`	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	`RO`	`0x0`
3	`timeout`	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	`RO`	`0x0`
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	`RO`	`0x0`

Bit	Name	Description	Access	Reset
1	`epdisbld`	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — No Interrupt 0x1 — Endpoint Disabled Interrupt	RO	0x0
0	`xfercompl`	Applies to IN and OUT endpoints. When Scatter/ Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** — **Description** 0x0 — No Interrupt 0x1 — Transfer Completed Interrupt	RO	0x0

dieptsiz7

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz7 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepctl8 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/ Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/ Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	`epdis`	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** / **Description** 0x0 — No Endpoint Disable 0x1 — Endpoint Disable	`RO`	`0x0`
29	`setd1pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** / **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	`WO`	`0x0`

<table>
<tr><th>Bit</th><th>Name</th><th>Description</th><th>Access</th><th>Reset</th></tr>
<tr><td>28</td><td>setd0pid</td><td>Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure.<table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>Disables Set DATA0 PID</td></tr><tr><td>0x1</td><td>Endpoint Data PID to DATA0)</td></tr></table></td><td>WO</td><td>0x0</td></tr>
<tr><td>27</td><td>snak</td><td>A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. </table>

Bit	Name	Description	Access	Reset
25:22	`txfnum`	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	`RW`	`0x0`
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	`RO`	`0x0`
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	`RW`	`0x0`

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — Not Active 0x1 — USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint8

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepctl9 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — Endpoint Enable inactive 0x1 — Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** / **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	RO	0x0
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** / **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0

Bit	Name	Description	Access	Reset
28	`setd0pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	`WO`	`0x0`
27	`snak`	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	`WO`	`0x0`
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	`WO`	`0x0`

Bit	Name	Description	Access	Reset
25:22	`txfnum`	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	`RW`	`0x0`
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	`RO`	`0x0`
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	`RW`	`0x0`

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** / **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** / **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint9

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint9 Fields

Bit	Name	Description	Access	Reset
14	`nyetintrpt`	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	`nakintrpt`	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	`bbleerr`	The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	`pktdrpsts`	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	`intknepmis`	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	`intkntxfemp`	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	`timeout`	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz9

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz9 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma9 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma9	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

diepctl10 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/ Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/ Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — Endpoint Enable inactive 0x1 — Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	`epdis`	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — No Endpoint Disable 0x1 — Endpoint Disable	`RO`	`0x0`
29	`setd1pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	`WO`	`0x0`

Bit	Name	Description	Access	Reset
28	`setd0pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Endpoint Data PID to DATA0)	`WO`	`0x0`
27	`snak`	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	`WO`	`0x0`
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	`WO`	`0x0`

Bit	Name	Description	Access	Reset
25:22	`txfnum`	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	RO	0x0
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — Not Active 0x1 — USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint10

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** / **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** / **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** / **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** / **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** / **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** / **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz10

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz10 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** **Description** 0x1 1 packet 0x2 2 packets 0x3 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

Bit	Name	Description	Access	Reset
25:22	`txfnum`	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	`RW`	`0x0`
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	`RO`	`0x0`
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	`RW`	`0x0`

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** / **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** / **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — Not Active 0x1 — USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint11

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz11 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** **Description** 0x1 1 packet 0x2 2 packets 0x3 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

Bit	Name	Description	Access	Reset
25:22	`txfnum`	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	RO	0x0
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** / **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** / **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint12

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
9	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — No interrupt 0x1 — BNA interrupt	RO	0x0
8	`txfifoundrn`	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — Fifo Underrun interrupt	RO	0x0
7	`txfemp`	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** — **Description** 0x0 — No interrupt 0x1 — Transmit FIFO Empty interrupt	RO	0x1
6	`inepnakeff`	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** — **Description** 0x0 — No interrupt 0x1 — IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	`intknepmis`	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** / **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	`intkntxfemp`	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** / **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	`timeout`	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** / **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** / **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz12

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/ DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

30	`epdis`	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — No Endpoint Disable 0x1 — Endpoint Disable	`RO`	`0x0`
29	`setd1pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	`WO`	`0x0`

Bit	Name	Description	Access	Reset
28	setd0pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Endpoint Data PID to DATA0)	WO	0x0
27	snak	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	WO	0x0

Bit	Name	Description	Access	Reset
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	RO	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint13

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

diepint13 Fields

Bit	Name	Description	Access	Reset
14	`nyetintrpt`	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** / **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	`nakintrpt`	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** / **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	`bbleerr`	The core generates this interrupt when babble is received for the endpoint. **Value** / **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	`pktdrpsts`	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** / **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	`RO`	`0x0`
8	`txfifoundrn`	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	`RO`	`0x0`
7	`txfemp`	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	`RO`	`0x1`
6	`inepnakeff`	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	`RO`	`0x0`

Bit	Name	Description	Access	Reset
5	intknepmis	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	intkntxfemp	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	timeout	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	ahberr	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. Value / Description 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. Value / Description 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

dieptsiz13

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

dieptsiz13 Fields

Bit	Name	Description	Access	Reset
30:29	mc	for periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. for non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — 1 packet 0x2 — 2 packets 0x3 — 3 packets	RW	0x0
28:19	PktCnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepctl14 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/ Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/ Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — Endpoint Enable inactive 0x1 — Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	`epdis`	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — No Endpoint Disable 0x1 — Endpoint Disable	`RO`	`0x0`
29	`setd1pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	`WO`	`0x0`

Bit	Name	Description	Access	Reset
28	`setd0pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Endpoint Data PID to DATA0)	`WO`	`0x0`
27	`snak`	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	`WO`	`0x0`
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	`WO`	`0x0`

Bit	Name	Description	Access	Reset
25:22	`txfnum`	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	`RW`	`0x0`
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	`RO`	`0x0`
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	`RW`	`0x0`

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** / **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** / **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** / **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint14

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
14	`nyetintrpt`	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — NYET Interrupt	RO	0x0
13	`nakintrpt`	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — No interrupt 0x1 — NAK Interrupt	RO	0x0
12	`bbleerr`	The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — BbleErr interrupt	RO	0x0
11	`pktdrpsts`	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** — **Description** 0x0 — No interrupt 0x1 — Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	txfifoundrn	Applies to IN endpoints Only. The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Fifo Underrun interrupt	RO	0x0
7	txfemp	This bit is valid only for IN Endpoints This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 No interrupt 0x1 Transmit FIFO Empty interrupt	RO	0x1
6	inepnakeff	Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core.This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 No interrupt 0x1 IN Endpoint NAK Effective interrupt	RO	0x0

Bit	Name	Description	Access	Reset
5	`intknepmis`	Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received with EP Mismatch interrupt	RO	0x0
4	`intkntxfemp`	Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received. **Value** **Description** 0x0 No interrupt 0x1 IN Token Received Interrupt	RO	0x0
3	`timeout`	In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is notasserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. **Value** **Description** 0x0 No interrupt 0x1 Timeout interrupy	RO	0x0
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — No Interrupt 0x1 — Endpoint Disabled Interrupt	RO	0x0
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** — **Description** 0x0 — No Interrupt 0x1 — Transfer Completed Interrupt	RO	0x0

dieptsiz14

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepctl15 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/ Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/ Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled -Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	`epdis`	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** **Description** 0x0 No Endpoint Disable 0x1 Endpoint Disable	`RO`	`0x0`
29	`setd1pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	`WO`	`0x0`

Bit	Name	Description	Access	Reset
28	`setd0pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/ Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/ Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Endpoint Data PID to DATA0)	`WO`	`0x0`
27	`snak`	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	`WO`	`0x0`
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	`WO`	`0x0`

Bit	Name	Description	Access	Reset
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	RO	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** — **Description** 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — The core is transmitting non-NAK handshakes based on the FIFO status 0x1 — The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — Endpoint Data PID not active 0x1 — Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — Not Active 0x1 — USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint15

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepctl0 Fields

Bit	Name	Description	Access	Reset
31	epena	When Scatter/Gather DMA mode is enabled, for OUT endpoints this bit indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is disabled(such as for buffer-pointer based DMA mode)this bit indicates that the application has allocated the memory to start receiving data from the USB.The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed In DMA mode, this bit must be Set for the core to transfer SETUP data packets into memory. **Value** — **Description** 0x0 — No action 0x1 — Endpoint Enabled	RO	0x0
30	epdis	The application cannot disable control OUT endpoint 0. **Value** — **Description** 0x0 — No Endpoint disable	RO	0x0

Bit	Name	Description	Access	Reset
27	snak	A write to this bit sets the NAK bit for the endpoint.Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set bit on a Transfer Completed interrupt, or after a SETUP is received on the endpoint. **Value** / **Description** 0x0 / No action 0x1 / Set NAK	WO	0x0
26	cnak	A write to this bit clears the NAK bit for the endpoint. **Value** / **Description** 0x0 / No action 0x1 / Clear NAK	WO	0x0
21	stall	The application can only Set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is Set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** / **Description** 0x0 / No Stall 0x1 / Stall Handshake	RO	0x0
20	snp	This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** / **Description** 0x0 / Snoop Mode disabled 0x1 / Snoop Mode enabled	RW	0x0
19:18	eptype	Hardcoded to 0 for control. **Value** / **Description** 0x0 / Endpoint Control 0	RO	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit, the core stops receiving data, even If there is space in the RxFIFO to accommodate the incoming packet. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** / **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
15	usbactep	This bit is always Set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces. **Value** / **Description** 0x1 USB Active Endpoint 0	RO	0x1
1:0	mps	The maximum packet size for control OUT endpoint 0 is thesame as what is programmed in control IN Endpoint 0. **Value** / **Description** 0x0 64 bytes 0x1 32 bytes 0x2 16 bytes 0x3 8 bytes	RO	0x0

doepint0

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint0 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — No interrupt 0x1 — NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — BbleErr interrupt	RO	0x0

Bit	Name	Description	Access	Reset
11	`pktdrpsts`	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** / **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0
9	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** / **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	`outpkterr`	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** / **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	`back2backsetup`	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** / **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0

Bit	Name	Description	Access	Reset
5	`stsphsercvd`	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** — **Description** 0x0 — No Status Phase Received for Control Write 0x1 — Status Phase Received for Control Write	`RO`	`0x0`
4	`outtknepdis`	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** — **Description** 0x0 — No OUT Token Received When Endpoint Disabled 0x1 — OUT Token Received When Endpoint Disabled	`RO`	`0x0`
3	`setup`	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** — **Description** 0x0 — No SETUP Phase Done 0x1 — SETUP Phase Done	`RO`	`0x0`

Bit	Name	Description	Access	Reset
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** / **Description** 0x0 No Interrupt 0x1 AHB Error interrupt	RO	0x0
1	`epdisbld`	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** / **Description** 0x0 No Interrupt 0x1 Endpoint Disabled Interrupt	RO	0x0
0	`xfercompl`	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** / **Description** 0x0 No Interrupt 0x1 Transfer Completed Interrupt	RO	0x0

doeptsiz0

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/ DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

Module Instance	Base Address	Register Address

doepctl1 Fields

Bit	Name	Description	Access	Reset
31	epena	Applies to IN and OUT endpoints. -When Scatter/ Gather DMA mode is enabled, -for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. -for OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. -When Scatter/ Gather DMA mode is enabled such as for buffer-pointer based DMA mode: - for IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - for OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: -SETUP Phase Done -Endpoint Disabled - Transfer Completed for control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 Endpoint Enable inactive 0x1 Endpoint Enable active	RO	0x0

Bit	Name	Description	Access	Reset
30	epdis	Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — No Endpoint Disable 0x1 — Endpoint Disable	RO	0x0
29	setd1pid	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** — **Description** 0x0 — Disables Set DATA1 PID 0x1 — Enables Set DATA1 PID	WO	0x0

Bit	Name	Description	Access	Reset
28	`setd0pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — Disables Set DATA0 PID 0x1 — Enables Endpoint Data PID to DATA0)	`WO`	`0x0`
27	`snak`	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — No Set NAK 0x1 — Set NAK	`WO`	`0x0`
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. **Value** — **Description** 0x0 — No Clear NAK 0x1 — Clear NAK	`WO`	`0x0`

Bit	Name	Description	Access	Reset
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	RO	0x0
20	snp	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	RW	0x0
19:18	eptype	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. h 1'b0'b0: Even (micro)frame 1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint1

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** — **Description** 0x0 — No Interrupt 0x1 — Transfer Completed Interrupt	RO	0x0

doeptsiz1

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

<tr><td>0x0</td><td>No Set NAK</td></tr>
<tr><td>0x1</td><td>Set NAK</td></tr>
</table></td><td>WO</td><td>0x0</td></tr>
</table>

Bit	Name	Description	Access	Reset
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. Value — Description 0x0 — No Clear NAK 0x1 — Clear NAK	`WO`	`0x0`
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value — Description 0x0 — STALL All Tokens not active 0x1 — STALL All Tokens active	`RO`	`0x0`
20	`snp`	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. Value — Description 0x0 — Disable Snoop Mode 0x1 — Enable Snoop Mode	`RW`	`0x0`
19:18	`eptype`	This is the transfer type supported by this logical endpoint. Value — Description 0x0 — Control 0x1 — Isochronous 0x2 — Bulk 0x3 — Interrupt	`RW`	`0x0`

Bit	Name	Description	Access	Reset
17	naksts	When either the application or the core sets this bit: -The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 The core is transmitting non-NAK handshakes based on the FIFO status 0x1 The core is transmitting NAK handshakes on this endpoint	RO	0x0
16	dpid	Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** **Description** 0x0 Endpoint Data PID not active 0x1 Endpoint Data PID active	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** **Description** 0x0 Not Active 0x1 USB Active Endpoint	RW	0x0
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint2

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doepint2 Fields

Bit	Name	Description	Access	Reset
14	`nyetintrpt`	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — NYET Interrupt	RO	0x0
13	`nakintrpt`	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — No interrupt 0x1 — NAK Interrupt	RO	0x0
12	`bbleerr`	The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — No interrupt 0x1 — BbleErr interrupt	RO	0x0
11	`pktdrpsts`	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** — **Description** 0x0 — No interrupt 0x1 — Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	outpkterr	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	back2backsetup	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	stsphsercvd	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	`outtknepdis`	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** — **Description** 0x0 — No OUT Token Received When Endpoint Disabled 0x1 — OUT Token Received When Endpoint Disabled	RO	0x0
3	`setup`	Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** — **Description** 0x0 — No SETUP Phase Done 0x1 — SETUP Phase Done	RO	0x0
2	`ahberr`	Applies to IN and OUT endpoints.This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** — **Description** 0x0 — No Interrupt 0x1 — AHB Error interrupt	RO	0x0
1	`epdisbld`	Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — No Interrupt 0x1 — Endpoint Disabled Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Applies to IN and OUT endpoints.When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. **Value** — **Description** 0x0 — No Interrupt 0x1 — Transfer Completed Interrupt	RO	0x0

doeptsiz2

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro) frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame.This field is not applicable for Scatter/ Gather DMA mode. **Value** **Description** 0x0 Disables Set DATA1 PID 0x1 Enables Set DATA1 PID	WO	0x0
28	`setd0pid`	Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. In non-Scatter/ Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/ Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** **Description** 0x0 Disables Set DATA0 PID 0x1 Enables Endpoint Data PID to DATA0)	WO	0x0
27	`snak`	A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit for an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 No Set NAK 0x1 Set NAK	WO	0x0

Bit	Name	Description	Access	Reset
26	`cnak`	A write to this bit clears the NAK bit for the endpoint. **Value** **Description** 0x0 No Clear NAK 0x1 Clear NAK	`WO`	`0x0`
21	`stall`	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 STALL All Tokens not active 0x1 STALL All Tokens active	`RO`	`0x0`
20	`snp`	Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 Disable Snoop Mode 0x1 Enable Snoop Mode	`RW`	`0x0`
19:18	`eptype`	This is the transfer type supported by this logical endpoint. **Value** **Description** 0x0 Control 0x1 Isochronous 0x2 Bulk 0x3 Interrupt	`RW`	`0x0`

<table>
<tr><th>Bit</th><th>Name</th><th>Description</th><th>Access</th><th>Reset</th></tr>
<tr><td>17</td><td>naksts</td><td>When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.
<table>
<tr><th>Value</th><th>Description</th></tr>
<tr><td>0x0</td><td>The core is transmitting non-NAK handshakes based on the FIFO status</td></tr>
<tr><td>0x1</td><td>The core is transmitting NAK handshakes on this endpoint</td></tr>
</table>
</td><td>RO</td><td>0x0</td></tr>
<tr><td>16</td><td>dpid</td><td>Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure.

Bit	Name	Description	Access	Reset
15	`usbactep`	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — Not Active 0x1 — USB Active Endpoint	RW	0x0
10:0	`mps`	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint3

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Module Instance	Base Address	Register Address
`usb0`	`0xFFB00000`	`0xFFB00B68`
`usb1`	`0xFFB40000`	`0xFFB40B68`

Offset: `0xB68`

Access: `RO`

doepint3 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** / **Description** 0x0 No interrupt 0x1 NYET Interrupt	RO	0x0
13	nakintrpt	The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** / **Description** 0x0 No interrupt 0x1 NAK Interrupt	RO	0x0
12	bbleerr	The core generates this interrupt when babble is received for the endpoint. **Value** / **Description** 0x0 No interrupt 0x1 BbleErr interrupt	RO	0x0
11	pktdrpsts	This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. **Value** / **Description** 0x0 No interrupt 0x1 Packet Drop Status interrupt	RO	0x0

Bit	Name	Description	Access	Reset
9	`bnaintr`	This bit is valid only when Scatter/Gather DMA mode is This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 No interrupt 0x1 BNA interrupt	RO	0x0
8	`outpkterr`	Applies to OUT endpoints Only This interrupt is asserted when the core detects an overflow or a CRC error for non-Isochronous OUT packet. **Value** **Description** 0x0 No OUT Packet Error 0x1 OUT Packet Error	RO	0x0
6	`back2backsetup`	Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. for information about handling this interrupt, **Value** **Description** 0x0 No Back-to-Back SETUP Packets Received 0x1 Back-to-Back SETUP Packets Received	RO	0x0
5	`stsphsercvd`	This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 No Status Phase Received for Control Write 0x1 Status Phase Received for Control Write	RO	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. **Value** **Description** 0x0 No OUT Token Received When Endpoint Disabled 0x1 OUT Token Received When Endpoint Disabled	RO	0x0
