

## Experiment 5 Frequency Modulation

### 1. Objectives:

- To demonstrate the general properties of frequency-modulated (FM) signals.
- To investigate the use of a PLL as an FM detector.

### 2. Prelab Assignment:

An unmodulated sinusoidal-carrier has an amplitude:  $A_c = \sqrt{2}V$  , and frequency:  $f_c = 25$  kHz. The carrier wave is frequency-modulated by a sinusoidal signal with a frequency:  $f_m = 2$  kHz, and amplitude:  $A_m$  V. The frequency sensitivity of the FM-modulator is 20 kHz/V.

- (a) Determine the values of  $A_m$  required to provide a modulation index:  $\beta = 0.2, 1$  and  $5$
- (b) Use table (1) to find the rms-value and location of each frequency component of the FM signal, with  $\beta = 0.2, 1$  and  $5$ ; use these rms-values to calculate the rms-values of the FM signals. How the calculated values of the FM signals compare with that of the unmodulated carrier?
- (c) For each value of  $\beta$  mentioned above, determine the approximate value of the transmission bandwidth of the FM signal, by using:
  - (i) the Carson's rule
  - (ii) the 99% bandwidth curve in Figure (1)

Table (1)  
Selective values of  $J_n(\beta)$

n	$J_n(0.1)$	$J_n(0.2)$	$J_n(0.5)$	$J_n(1.0)$	$J_n(2.0)$	$J_n(5.0)$	$J_n(10)$	n
0	1.00	0.99	0.94	0.77	0.22	-0.18	-0.25	0
1	0.05	0.10	0.24	0.44	0.58	-0.33	0.04	1
2			0.03	0.11	0.35	0.05	0.25	2
3				0.02	0.13	0.36	0.06	3
4					0.03	0.39	-0.22	4
5						0.26	-0.23	5
6						0.13	-0.01	6
7						0.05	0.22	7
8						0.02	0.32	8
9							0.29	9
10							0.21	10
11							0.12	11
12							0.06	12
13							0.03	13
14							0.01	14

Figure (1)

### 3. Equipment:

- Function generators Tektronix CFG 253
- Model SR760 FFT Spectrum Analyzer
- Oscilloscope Tektronix TDS 340A
- Dual dc-power supply
- LPF module
- EVM dB scale

### 4. Procedure:

#### A The Voltage-Frequency Transfer Characteristic of a Voltage-Controlled Oscillator

1. Use one of the signal generators (referred to here as generator 1) to generate a sinusoidal waveform of 10 kHz. Apply a NEGATIVE dc-voltage (referred to here as E) to the "VCF-INPUT" terminals of generator 1; E is set at any value between -0.1 and -2.5 volts. Use the oscilloscope to adjust the output level of the generator to 2.83 V (p-p); display this signal on the spectrum analyzer. The analyzer now displays the spectrum of an unmodulated carrier, whose frequency will be referred to as  $f_c$ ; the rms-value is 1V. [You may have to fine adjust the output level to achieve a 1V rms].
2. For each setting value of E, as in table (2), measure  $f_c$ . Use Graph (1) to plot the voltage-frequency transfer characteristic of the generator; determine the frequency sensitivity,  $K_o$  in kHz/V.

Table (2)

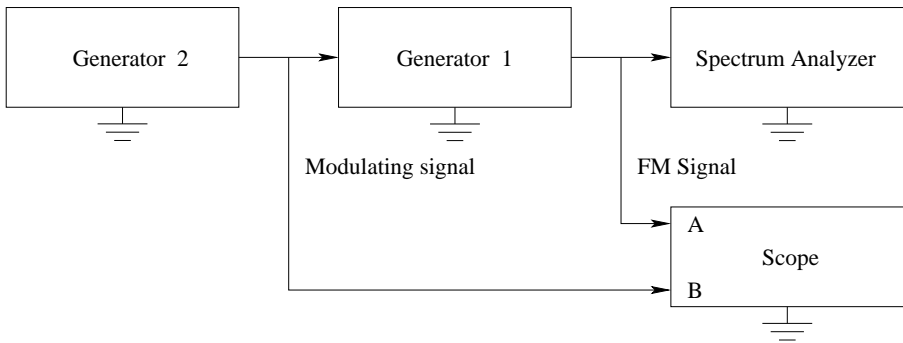

E (volts)	-0.1	-0.5	-1	-1.5	-2	-2.5
$f_c$ (kHz)						

Graph (1)

B General Properties of FM Signals

- 3. Use the other signal generator (referred to here as generator 2) to generate a sinusoidal waveform with frequency ( $f_m$ ) of 2 kHz. This waveform will be used as a modulating signal. For now, set the amplitude level ( $A_m$ ) of the waveform to zero. Apply the waveform to the "VCF-input" terminal of generator 1. leave the oscilloscope and the frequency analyzer as before. Set the frequency of the output of generator 1 to 25 kHz. The FM-measuring system is now set as shown in Figure (2).

Graph (2)

- 4. Use the value of  $K_o$  (found in step 2) to set the output level ( $A_m$ ) of generator 2 to provide an FM-modulated signal with:

- carrier frequency,  $f_c$  @ 25kHz
- amplitude,  $A_c$  of 1.41 V (peak)
- modulation index (B) of 0.2 @  $f_m = 2\text{kHz}$

Use Table (3) to list the rms-value and location of each frequency component in the spectrum of the FM-modulated signal; ignore the components with rms-values  $< 0.01$  V.

5. Repeat step 4, for: i) B = 1, and ii) B = 5.

Table (3)

B	Frequency components (kHz)	rms-value (V)
0.2		
1		
5		

6. Calculate the total rms-value of the FM-modulated signal for each value of B, and record in table (4).

Table (4)

B	0.2	1	5
Total rms-value (V)			

7. With  $A_m$  set to provide  $B = 5$  and  $f_m = 2\text{kHz}$ , change the modulating frequency  $f_m$  to 200 Hz. What is the value of the modulation index now?

B =

Use Graph (2) to sketch the spectrum of the FM modulated signal. What is the approximate value of the FM-signal bandwidth?

BW =

Graph (2)

8. Set  $f_m$  @ 1kHz and  $A_m$  @ zero. Gradually increase  $A_m$  until a spectral null occurs at the carrier frequency  $f_c = 25\text{kHz}$ ; measure the value of  $A_m$  and determine the corresponding modulation index B.

$$B =$$

9. Increase further the value of  $A_m$  until a second spectral null occurs at  $f_c$ ; measure  $A_m$  and determine the value of B.

$$B =$$

### C The PLL as an FM Detector

10. Connect the PLL-unit circuit as shown in Figure (2) of Exp. 5; adjust R1 to achieve a free-running frequency of 25 kHz.
11. Connect the block diagram in Figure (3); set  $f_c$  @ 25 kHz,  $A_c$  @ 0.5V (peak),  $f_m$  @ 100 Hz, and B @ 1 (by adjusting  $A_m$ ).

Figure (3)

The LPF module (which is a second-order Butterworth biquad) is used to provide extra low-pass filtering for the FM-demodulated output signal,  $V_o$ . Display the modulating signal  $V_i(t)$  and the demodulated output  $V_o(t)$  on the oscilloscope [use AC coupling].

12. Test the LPF module separately, and set its cut-off (-3dB) frequency @ 1 kHz. Run a frequency response test for  $(V_o/V_i)$  in dB vs the frequency,  $f_m$  in Hz, for the block diagram in Figure (3); use at least seven strategically-located frequency values in the range:  $100\text{ Hz} \leq f_m \leq 4\text{ kHz}$ . Use Graph (3) to plot  $(V_o/V_i)$  in dB vs  $f_m$  in Hz.
13. Once more test the LPF module separately, and set its cut-off frequency @ 4 kHz; repeat as in step 12.

Graph (3)

### 5. Comments and Conclusions:

1. Compare your results in table (3) with those calculated in the prelab assignment. Comment on any deviations.
2. A spectral null did occur at the carrier frequency of the FM-modulated signal for specific values of  $B$ . Explain briefly the effect of this phenomenon on:
  - (a) the total rms-value of the FM signal
  - (b) the rms-value and location of each component in the spectrum
3. The frequency-response plot found from step 13 is very much different from that found in step 12; why?
4. Use the frequency response from step 13 to estimate the natural frequency and the damping ratio of the second-order locked loop.
